We are indebted to Lieut.-Col. R. C. Grant for generously assisting us with the records of these cases.

A CASE OF COMBINED INTRA-UTERINE AND EXTRA-UTERINE PREGNANCY

BY

R. B. LEECH, M.B., B.Ch.

C.M.S. Hospital, Mengo, Uganda

The following case of combined intra-uterine and extra-uterine pregnancy is reported because of the rarity of the occurrence.

Case History

The patient comes from a village some forty miles away where we have one of our district maternity centres. I visit this centre every fortnight to hold a general clinic and examine any abnormal obstetric cases, which the trained African midwife collects for me in her routine ante-natal examinations. In this way I had the good fortune to examine the patient three times before she finally came into hospital here, though on none of these occasions did I suspect the true diagnosis.

Ante-natal Observations.—She was an African woman aged about 30, who had had three normal pregnancies and labours, the last some eighteen months previously. I first saw her on September 5, 1940, and diagnosed a pregnancy of four months' duration, though she said she was still having short periods at that time. I was next asked to see her on February 20, 1941, and found on abdominal examination a uterus of about nine months' gestation with swellings somewhat resembling a foetal head on each side of it. I considered the possibility of twins, but the findings did not really support this diagnosis; so, remembering the clinical axiom that common conditions commonly occur, I made the provisional diagnosis of fibroids, though I was puzzled at not having recorded any suspicion of them at my previous examination. I advised her to come into hospital a little later.

From Delivery to Laparotomy.—She went into labour on March 5, and was delivered in the maternity centre by the midwife after a normal labour; the baby was a fully developed boy weighing 5½ lb. I saw her, however, on March 6, and found the para-uterine swellings still present; I still thought they might be fibroids, but regret that I made no more than a perfunctory examination, as all seemed well. The next day the patient began complaining of abdominal pain, which slowly increased but was not severe enough to prevent her being discharged from the maternity centre a week later. The pain continued to grow worse, and she came into the central hospital here on account of it on March 27. The baby was somewhat under-nourished, as no breast milk had come in. On examination the woman was obviously ill and in pain. There was a fair pulse and some pallor. On palpation of the abdomen and vaginal examination I could come to no other conclusion but that there was an intraperitoneal extra-uterine foetus present, and I was almost convinced that I heard a foetal heart. I left her to recuperate from the journey, and performed a laparotomy the next day.

Findings at Operation.—The peritoneal cavity was filled with straw-coloured clear fluid containing large fibrinous clots. Much of the peritoneum and the whole of the great omentum were covered in a thick jelly-like material. A foetus was lying free among the coils of intestine and there was a fair pulsation in the cord. I delivered the baby, and found the ruptured sac arising from the placenta, which was attached by what amounted to little more than a thick pedicle; this sprang from the right broad ligament just behind the fimbria in the position of the ovary, there being no direct connexion with the Fallopian tube. There were also two thick bands of adhesions running

from the great omentum to the sac and ending in two subsidiary placentae near the main one. The uterus appeared to be involuting normally. Removal of the sac and placentae was not difficult, and the patient is now making a good recovery. The baby was a boy weighing 6 lb., and was without evident abnormality save for clots of what seemed to be fibrin adherent to the skin in places. It breathed weakly for about half an hour, but all the usual care could not maintain life.

Commentary

The frequency of extra-uterine pregnancy is not easy to ascertain, but Schumann (1921) calculated the frequency for one year in one town to be one in every 303 pregnancies. Mall (1915) further calculates that 1% of extra-uterine pregnancies go to full term, and notes that the foetus in these cases is especially liable to maldevelopment. Cases of extra-uterine associated with intra-uterine pregnancy—referred to by Parry (1876) as combined pregnancy—have been reported a number of times, 306 having been traced by Subodh Mitra (1940); but only ten of these (according to Novak, 1926) have resulted in the birth of both children alive.

Although no ovarian tissue was found by the pathologist in the wall of the amniotic sac, the position of the placental site in this case suggested strongly that the pregnancy originated in the ovary. Ovarian pregnancy is the least common type of extra-uterine gestation, only forty-one recorded cases having been traced by Lockyer (1917); but Williams (1923) considers that a higher proportion of ovarian pregnancies go to full term than do pregnancies of tubal origin. It is of interest to note, too, that no long period of sterility preceded this pregnancy; this perhaps suggests that the mechanism believed to be largely responsible for tubal gestation—namely, some form of obstruction in the tube—did not come into play.

I can offer no special explanation of the fact that the patient had short periods up to within six months of delivery of full-term children, but have an impression that slight menstruation may continue after conception more often than in England, although histories here are very unreliable.

It seems likely that the amniotic sac of the extra-uterine foetus ruptured when the abdominal pain began, two days after the delivery of the uterine pregnancy. It was probably due to some sudden abdominal strain by the patient, or possibly even to an abdominal examination. The action of the amniotic fluid within the peritoneal cavity—that of a mild irritant—is of interest.

The breasts secreted very little milk even after the delivery of the second baby, owing perhaps to the general debility of the patient, so that no deduction can be drawn as to the inhibitory action of the extra-uterine gestation on lactation.

R. M. Greenhalgh (*Wisconsin med. J.*, 1941, 40, 25), who reviews the literature and records his observations on 100 cases, comes to the conclusion that the disease called "roseola infantum" by Zahorly in 1910 and "exanthema subitum" by Veecher and Hempelmann in 1921 is a clinical entity. It affects children during the first two years of life and seems to confer immunity. Its characteristic features are a febrile period of three days, and after the temperature has become normal a rash lasting about two days. The blood shows a relative lymphocytosis and often a lymphopenia. There are no complications or sequelae. The aetiology is unknown. The incubation period is about ten days.

UNUSUAL RETICULOCYTOSIS IN AN UNTREATED CASE OF PERNICIOUS ANAEMIA

BY

W. TREVOR COOKE, M.D., M.R.C.P.

Medical Registrar, Birmingham United Hospital

The following case caused some difficulty in diagnosis owing to the finding of reticulocytosis of more than 30% in the presence of severe anaemia and a recent history of jaundice.

Case Report

Mrs. X., aged 30, had always been perfectly well until February, 1939, when she complained of feeling run down, with loss of appetite and energy. She had also lost some weight. Her private doctor, having treated her symptomatically with an iron mixture without response, referred her to hospital. There, no history could be elicited to account for her symptoms, while it was noted that she looked sallow and pale, although her mucous membranes were of a good colour. There was also marked pyorrhoea. Radiographs of her chest were normal, while a blood count showed a moderate anaemia: red cells, 2,570,000; Hb, 49%; colour index, 0.95; white cells, 12,000—polymorphs 72%, eosinophils 1.5%, lymphocytes 24.5%, mononuclears 2.5%. The red cells showed some anisocytosis and poikilocytosis. On account of these findings and because there had been no response to iron therapy, hepamult was prescribed in addition, and she was advised to have her teeth extracted. This was done, and she next attended the hospital two months later, feeling very much better. A blood count on this occasion showed: red cells, 4,600,000; white cells, 9,600; Hb, 92%; colour index, 1.

Shortly after this she married and moved to the Birmingham district, where she was well until March, 1940, when she again became pale and nauseated. She improved with some medicine from her doctor, but again relapsed at the beginning of July. She then became very nauseated and developed epigastric pain and jaundice—so much so that the jaundice was commented upon by her friends. She lost weight again and a great deal of energy. Headaches were very severe. She had had no haematemesis and no upset in her menstrual functions, but some slight bleeding from the rectum had occurred. There was no family history of any blood disorder. She was referred to the General Hospital for further advice one month after the onset of her most recent attack.

She was there noted to be very pale—on first appearances suggestive of a patient with a bleeding duodenal ulcer. She had a smooth tongue, a marked haemic murmur, and slight tenderness in the epigastrium. Vaginal and rectal examinations were negative. Investigations showed a macrocytic type of anaemia with 42% haemoglobin and a positive indirect and slight direct van den Bergh test (serum bilirubin, 1 unit). She was therefore admitted to the Queen Elizabeth Hospital (August 6) for further investigation. Physical examination was essentially the same as that in the out-patient department, although there was divergence of opinion as to the presence of splenic enlargement. Her faeces were benzidine-negative.

The blood examination on admission showed marked reticulocytosis (red cells, 1,420,000; reticulocytes, 33.4%; Hb, 34%; colour index, 1.21; white cells, 4,600—polymorphonuclears 21.25%, eosinophils 1.25%, lymphocytes 74.5%, monocytes 2.7%, neutrophil myelocytes 5.25%), while the stained films revealed great anisocytosis, slight poikilocytosis, and marked polychromasia, the platelets appearing normal.

Inquiry into her dietetic habits disclosed that she did not eat excessive amounts of meat, that she was accustomed to have liver regularly once a week, and that she had had no liver therapy from her doctor. A diagnosis of chronic haemolytic anaemia appeared probable, and Dr. T. W. Lloyd was asked to carry out investigations with this in view. On August 9 his examination with heparinized blood gave the following results:

Red cells	2,110,000
Haemoglobin	51%
Colour index	1.2
Haematocrit	21.7%
Mean cell volume	103 cubic microns
Mean cell haemoglobin concentration	32.4%
Reticulocytes	31%
White cells	1,900 per c.mm.
Polymorph neutrophils	25.5%
Eosinophils	0.5%
Premyelocytes	1%
Lymphocytes	72%
Monocytes	1%
Normoblasts	2%

A striking feature of the neutropenia, which in itself was unusual in the presence of such active red cell regeneration, was the absence of non-segmented forms, all the polymorphs being heavily segmented.

The fragility began in 0.45% and was complete in 0.25% saline, a slight increase as compared with normal. The lecithin resistance was greatly increased, thus:

Concentration of Lysocleithin	Haemolysis of Patient's Cells	Haemolysis of Control Cells
1/32	100%	100%
1/64	52%	100%
1/128	0	15%
1/256	0	0

This test was considered to exclude acholuric family jaundice. The Price-Jones curve (250 cells) showed very marked macrocytosis, mean diameter 8.78 μ . It was a homogeneous curve, and when decomposed by the method of Mogesen the main component had a mean diameter of 8.75 μ and contained 100% of the cells drawn.

The serum was examined for haematin (methaemalbumin) by Schumm's method and by spectroscopic analysis. Tests that proved to be negative were also carried out by the method of Damashek for the presence of isohaemolysins. The Donath-Landsteiner test for paroxysmal (cold) haemoglobinuria was also negative.

In the meantime the patient was improving on a normal hospital diet without any medication. A fractional test meal showed the presence of achlorhydria, and a laevulose-tolerance test gave a normal result. On admission the van den Bergh test had shown a positive biphasic reaction and a positive indirect reaction with an icterus index of 10. One month later the indirect test was still faintly positive with the icterus index at 7.4 units, while eight weeks after admission both the direct and indirect tests were negative.

In view of these findings the diagnosis of pernicious anaemia was put forward. Accordingly a test dose of liver extract

Chart showing the blood counts during stay in hospital and the response to liver therapy

(anahaemin 2 c.cm. intramuscularly) was given when the red cells were 2,300,000 and the reticulocytes had fallen to less than 1%. A reticulocyte response of 10% was obtained on the sixth day following, falling to normal six days later. The achlorhydria was shown to be absolute, no HCl being secreted in response to 1.5 mg. of histamine. Liver extract was continued with complete relief of her symptoms and restoration of the blood picture to normal (see Chart).

The patient has maintained good health for fourteen months on a fortnightly dose of 2 c.cm. of anahaemin. The most recent blood count showed: red cells 4,640,000, Hb 98%, and colour

index 1.05; the van den Bergh test was negative. The Price-Jones curve is now within normal limits, with a mean diameter of 7.014μ .

Discussion

The striking feature of this case was the persistence of a reticulocytosis of over 30% for at least forty-eight hours in a patient who had received no treatment and the difficulty in diagnosis that this finding caused. Such a reticulocytosis, taken in conjunction with the apparently rapid onset and a history of other attacks and of jaundice, seemed to indicate haemolytic anaemia. Against this the presence of glossitis was one small point, but the negative findings of the special investigations and the subsequent findings of complete achlorhydria threw further doubt on the original diagnosis. Finally, the reticulocyte response to a test dose of liver extract associated with a rise of red cell content indicated an absence of haemopoietic factor. Such a response would be exceptional in any of the haemolytic types of anaemia. In fact, all the findings seem, to indicate a diagnosis of pernicious anaemia in spite of such an unusual reticulocytosis.

Little mention is made in the literature regarding the number of reticulocytes present during the relapse phase. Sturgis and Isaacs (1938) state that spontaneous crises are sometimes seen with 7 to 8% of reticulocytes. Whitby and Britton (1939) note that occasionally pronounced reticulocytosis is present, but do not give figures. A rapid survey of other relevant publications failed to throw any light on the problem. The marked reticulocytosis in this case, following a submaximal dose of the intrinsic factor, should be due to the reaction of a young and comparatively healthy bone marrow, which has not yet become exhausted in the effort to keep up the supply of corpuscles from inadequate material. The same amount in an older person would, no doubt, only have given the reticulocytosis that is usually noted during remissions (7 to 10%).

It is interesting to speculate on the reason why this patient, accustomed to a regular and adequate diet, should suddenly relapse and with apparently equal rapidity begin to regenerate her red blood corpuscles. While we know that absence of the intrinsic factor leads to the development of pernicious anaemia, there is no definite knowledge as to the factors that lead to its disappearance. It is frequently suggested that the stomach in persons completely achlorhydric is especially disposed to gastritis, which will eventually lead to the suppression of the intrinsic factor. The history in this case supports such an idea. Dental sepsis, often put forward as an aetiological factor in earlier days, no doubt caused some degree of gastritis to initiate the first relapse. The last relapse, ushered in as it was by nausea, vomiting, epigastric pain, and jaundice, is very suggestive of gastritis with an associated "duodenitis." The relapses would then be due to a suppression of the intrinsic factor and the remissions be due to improvement in the gastritis, with a consequent return to a more normal diet and the reappearance of a small amount of intrinsic factor (cf. pernicious anaemia of pregnancy). The diagnosis of gastritis is not altogether unjustified, as for a short period after starting liver therapy the patient had nausea, vomiting, and epigastric discomfort which were relieved by a simple bismuth mixture, and also on one or two occasions since her discharge from hospital she has had short bouts of epigastric discomfort.

Summary

A case of pernicious anaemia in a young married woman aged 30 is reported. The patient presented the unusual feature of reticulocytosis of 33.4% in the absence of any previous treatment.

Administration of liver extract gave complete relief of symptoms and restored the blood picture to normal.

Good health has been maintained on a fortnightly dose of 2 c.cm. of anahaemin.

I wish to thank Prof. W. H. Wynn for permission to report this case and for his criticism and advice in preparing the manuscript; also Dr. T. W. Lloyd and Dr. A. L. Peeney for their detailed blood examinations and help in the diagnosis of this case.

Acquired Immunity to Blood Transfusion Reactions: A New Phenomenon

Reactions occurring during the transfusion of blood are for clinical purposes commonly divided into two main groups: haemolytic and non-haemolytic. The onset of the reactions is similar, but as a rule the former becomes progressively worse for hours or days, and often ends fatally; while the latter, alarming though it may appear, usually expends itself within an hour, leaving no observable evidence of permanent damage. It is with the latter type that this paper is concerned.

It has been our experience that the recipient, having suffered this reaction, is for some time immune to further reaction to the same blood. Hence the transfusion may with complete safety be resumed soon after subsidence of the response.

FIRST OBSERVATIONS

Our first observation of this kind was made on a male Hindu aged 18 to whom a transfusion was given following amputation of a leg after a crush injury. Fifty c.cm. or so of 5% glucose solution alone was first used, and then the blood was started at the rate of about 50 drops a minute. When 150 c.cm. of blood had run in, the patient developed a severe chill, the pulse became rapid and thready, and there was marked pallor. The transfusion was discontinued promptly, the foot of the bed was elevated on shock-blocks, and hot-water bags and blankets were applied. One c.cm. of adrenaline was injected intramuscularly. The reaction, which was most violent, ran its course and subsided completely within an hour. A careful check was made of the blood, but no error was found either in the grouping or in the cross-agglutination tests. Also, the citrate solution had to be considered, although our intravenous solutions had produced no such symptoms in some hundreds of administrations. Accordingly, 50 c.cm. of the glucose-saline solution was given by vein to each of three otherwise healthy fracture patients, and 20 c.cm. of 3.8% citrate solution was injected intravenously in two other afebrile individuals. None of these subjects developed chills or fever, nor was there any significant variation in the pulse rate as a result of the injections. The reaction observed in our patient was therefore purely from the blood, and was characteristic of the non-haemolytic type, being in general essentially the same as the others of this type which we had seen here and elsewhere.

THE HYPOTHESIS OF ANAPHYLAXIS

Because of its typical character this case was chosen to test a hypothesis which had occurred to us: that the reaction is anaphylactic in nature. If this were an anaphylactic response the patient had very likely become desensitized, and it should be possible, therefore, to continue the transfusion without further response. Accordingly, some five hours after the patient's recovery the transfusion was resumed, the blood being run into the vein very slowly, while careful watch was kept for any untoward symptoms. The transfusion was completed without the slightest reaction.

With this as a precedent, in every other case of transfusion shock since then—twelve in all—we have merely interrupted the transfusion long enough to permit complete recovery from the reaction and to check the cross-matching. In all cases the readministration of blood to a total of about 500 c.cm. proceeded without event.

The following table summarizes the essential details of the cases:

Case	Age	Sex	Group	Amount of blood before Reaction	Interval between Transfusion
1	18	M	B (III)	c.cm. 150	hours 5½
2	55	M	B	25	3½
3	18	M	B	70	15
4	24	M	B	70	3
5	27	M	B	400	5
6	22	M	B	350	2½
7	17	M	B	200	5½
8	10	M	B	120	5½
9	28	M	B	150	22
10	35	M	B	150	7½
11	31	M	O (IV)	70	22
12	37	M	B	250	8

CONCLUSIONS

We can find in the literature no satisfactory explanation for the non-haemolytic reactions—that is, where, as here, fresh blood is used. Impurities in the rubber tubing, particles of old blood left in the needle, the use of blood from a donor in the post-prandial period, are among some of the explanations given. Such reasons seem inadequate, for we do not observe reactions from saline and glucose injections when the same apparatus as that used for blood transfusions is employed, and our blood donors were all drawn from the local prison, where the rule prohibiting the taking of food before the giving of blood is strictly enforced.

The symptoms of this type of reaction to blood transfusion are certainly very similar to those of anaphylactic shock in general. And our finding that soon after recovery the transfusion could be resumed without response suggests to us that these reactions are indeed anaphylactic in nature. Accordingly, the reaction is to be considered a process of desensitization. We do not venture to guess the nature of the antigenic substance.

Of the twelve cases reported, eleven belonged to Group B (III), and all the patients were males. (Our patients are limited to this sex entirely.) The predominance of Group B in the transfusion reactions here seems to be only a coincidence. Five Group B patients not mentioned had no reaction at all to transfusion. There have been reactions of this kind in only two cases belonging to Group O (IV), one of which is reported here (Case 11). In the other case a direct transfusion was given and was not repeated, so no mention of it is made above.

The practical importance of this phenomenon is self-evident. Blood which has caused such reactions need not be discarded, our experience showing that after checking the cross-agglutination the transfusion may be resumed safely soon after the recipient has recovered from the reaction.

We are indebted to Dr. C. M. Van Allen, chief surgeon of the Bikaner State Hospital, for his guidance and kind criticism.

C. E. DAS GUPTA, L.C.P.S.

Bikaner, Rajputana

Bikaner State Hospital.

M. J. Reuter and R. Nomland (*Wisconsin med. J.*, 1941, 40, 196), who record three personal cases in women aged 52, 56, and 72, state that cutaneous metastatic cancer may be associated with inflammatory signs. The clinical features are closely allied to the inflammation of erysipelas, but there is no chill, fever, prostration, or leucocytosis. The diagnosis is difficult and a biopsy is usually required. As inflammatory metastatic carcinoma secondary to primary cancer of the breast is common, any inflammatory lesion of the skin of or about the breast which does not subside in two or three weeks warrants a biopsy for diagnosis. Histologically the inflammatory signs are due to extensive lymphatic blockage by cancer cells which causes oedema.

Reviews

PLANNING FOR HEALTH

National Health Services and Preventive Methods for Improving National Health. By Dame Janet Campbell, M.D., and H. M. Vernon, M.D. (Pp. 46. 9d.) London: British Association for Labour Legislation.

In his introduction to this pamphlet of the British Association for Labour Legislation its chairman, Mr. H. Graham White, M.P., says: "We must prepare for a real extension of national health insurance (including dependants of the insured), a reorganization of our hospital system, and a change in the position of the medical profession in the community." As to the first two of these aims there is a considerable measure of agreement; what the third means is not at all clear. In the first of his *Collected Addresses* the late Wilfred Trotter, comparing the profession of medicine with those of the Church and the Law, describes it as having, unlike them, "had no direct influence in the work of government. It has therefore had to submit to its duties being piled up as occasion arose with no resource for securing a due compensation of privilege and immunity. . . . The result is that it finds itself of all professions the least in command of social prestige, the least privileged, the most exposed, and the hardest worked. I do not think it is to be deplored. It has put medicine in the very small class of professions in which it is possible for men and women to pursue the dying ideal that an occupation for adults should allow of intellectual freedom, should give character, as much chance as cleverness, and should be subject to the tonic of difficulty and the spice of danger." A profession of which this could be said by one of the wisest of its members may well be watchful of proposals ostensibly intended to change its position in the community; and his statement affords criteria by which the desirability of any profound changes may well be tested.

The pamphlet under review is definitely designed to promote some such changes. It is not a joint production of its authors in the ordinary sense, but consists of two independent essays—one by Dame Janet Campbell on "National Health Services," the other by Dr. H. M. Vernon on "Preventive Methods for Improving National Health." The latter is a useful contribution, setting out clearly a number of facts relative to social and industrial health, and showing that "there are at our disposal many simple preventive measures, not dependent on medical aid, which, if adopted, will cause a considerable rise in the average standard of health and physique in the nation." The facts will probably be familiar to a majority of readers, but it is to be hoped that there will be others to whom they will afford a fresh stimulus to action. Two opinions expressed are particularly noteworthy: that "occupational environment is not nearly so important a factor in controlling the health of the nation as social environment"; and that "of all the social conditions met with in the home maternal care comes next in importance to nutrition and counts for more than the standard of the housing." If to these be added a third—that every responsible individual can largely determine his own environment—we have some valuable guides towards reform.

Dame Janet Campbell's essay has a more direct bearing upon the position of the medical profession. Here again the facts of the situation are set out clearly, though they are now quite familiar to most readers. So are the defects of the present medical provision. But in this connexion the author is not quite accurate or fair. She underestimates both the curative and preventive work of the general practitioner, though admitting his potentialities for good; and it

is both inadequate and misleading to say of insurance practice that "its scope is strictly limited and confined in the main to minor diseases, many of which are treated at the surgery with a bottle of medicine. . . . The hurried work of the busy private surgery makes it impracticable for the most conscientious doctor to give the full time and attention needed by many of his patients." It is evidently difficult for one whose main professional work has been that of a departmental official to envisage the actual extent and efficiency of the work of general practitioners as a class.

The main change advocated by Dame Janet Campbell is apparently the general establishment of "health centres" where practitioners, all on a whole-time salaried basis as officers of the local authority or central department, would be jointly responsible for medical attendance, an attempt being made to maintain an individual relationship between doctor and patient so far as possible. There may be densely populated and very poor urban areas where such an arrangement would prove convenient and help the amenities of medical residence and practice; but, even so, why the whole-time salaried basis of remuneration? And are not areas of this character to be eliminated after the war? A little reflection must show that such an arrangement would be unnecessary, inconvenient, unacceptable, or quite impracticable in most residential and in almost all rural areas. Moreover, it would inevitably alter the traditional relationship between patient and doctor. The atmosphere of the consulting-room would tend to change from that of a purely private, confidential, friendly interview to that of a less sympathetic investigation by a public official sharing his duties with others and having only a minor interest in the individual. There is no hint in the pamphlet that there are other solutions, but it is to be hoped that all who read it will not be content without a wider knowledge of these.

STATISTICAL LITERATURE

The Second Yearbook of Research and Statistical Methodology. Books and Reviews. Edited by Oscar Krisen Buros. (Pp. 344. \$5.00.) New Jersey: The Gyphon Press. 1941.

The primary object of this handsome volume is to help students and teachers of statistics to discriminate between good and bad statistical books. To that end the editor has reprinted reviews of statistical books published in one or more of 283 American or British journals. The books reviewed are arranged alphabetically by author's name and cover a wide field—elementary textbooks, volumes of mathematical tables, monographs, and books like Prof. Bernal's *The Social Function of Science*, which deals with social relations. A subject index enables the reader to turn to the reviews of books on topics in which he is interested. We have no doubt that any statistician would find this volume interesting and instructive, and not much doubt that, if those for whom it is designed would use it, they would learn a good deal, although, as the editor points out, the reviews vary in competence and a beginner can hardly discriminate between competent and incompetent criticisms.

The aim of the editor is praiseworthy, but we doubt whether the scale is not too large. The reviews, although restricted to books written in or translated into English, cover more than 350 large pages. It might be better to restrict the connotation of the term "statistical" more narrowly (it is, for instance, hard to see what on earth Mr. Otto Eisenschimi's paper on the alleged crimes of historical critics, a review of which occupies almost a page, has to do with statistics, however defined) and to select the reviews printed. We realize the difficulty of this. If, for instance, one printed the reviews of a book intended for medical readers which appeared in medical journals and

no others, some important criticism by a mathematical writer might be lost. But an editorial committee should be able to guard against that risk and, without quite drastic curtailment, the undertaking will, we think, prove beyond human powers.

TECHNIQUE FOR THE THEATRE

Instruments, Appliances, and Theatre Technique. By Evelyn Pearce, Senior Sister Tutor, Middlesex Hospital. (Pp. 226; illustrated. 6s. net.) London: Faber and Faber, Ltd. 1941.

Instruments, Appliances, and Theatre Technique is the title of a small, well-illustrated book by Miss Evelyn Pearce, who has already written several textbooks which have made her name well known to the members of the nursing profession. Her latest work has been produced to meet a demand on the part of those engaged in teaching and training probationer nurses, assistant nurses, nursing auxiliaries, and orderlies in hospitals both in this country and with our Forces overseas. As Miss Pearce tells us, the instruments employed in surgery are numerous and many are highly specialized, so that too wide a field could not be covered. Nevertheless the field so covered is a fairly representative one and well up to date, and includes examples of recent types of blood transfusion apparatus. Some obsolete appliances could, with advantage, be omitted from a second edition, particularly Cline's, Neville's, and Marshall's ham splint, Liston's knee splint, and the jointed arm and hollowed, angular, wooden arm splints. There is nothing to be gained by overloading the minds of tired nurses with the names and details of such pieces of apparatus, which are at present merely of historical interest. The same remark applies to certain little-used instruments such as Mosley's fascia forceps, Liston's naevus needle, Doyen's needle, etc. On the whole, however, the selection of material, always a difficult matter in a book such as this, has been good. Special apparatus for ear, nose, and throat and ophthalmic surgery, anaesthesia, lumbar puncture, etc., is included. The text is adequate, well printed, and clear, the illustrations are good, and the book is of convenient size. It should have a wide appeal to all who may be called upon to form part of the team of an operating theatre here or abroad, in civil life or in the Services. As a guide to such it can be strongly recommended. Miss Pearce is to be congratulated on thus providing for the needs of a large number who are in training at present and who will in time be succeeded by numerous others.

PLASTIC SURGERY

Chirurgie Réparatrice et Correctrice des Téguments et des Formes. By L. Dufourmentel. (Pp. 408; illustrated; paper cover. \$3.00.) Paris: Masson et Cie.

The author was a pupil of Prof. Pierre Sebileau, who contributes a preface to this work, and was one of the most active of the French plastic surgeons during and after the war of 1914-18. He defines "reparative surgery" as the art of reconstituting tissues or organs which are missing or have been accidentally destroyed, while "corrective surgery" is the art of giving a normal aspect to malformed or accidentally deformed organs. The author points out that these terms must necessarily overlap to some extent. The first chapters are devoted to general methods, among which is included a section on emergency plastic surgery. The contents of the other chapters are well indicated by their titles: corrective surgery of the skin, reparative surgery of the skin, corrective surgery of the nose, reparative surgery of the nose, fronto-orbital reparative surgery, corrective surgery of the maxillae, reparative surgery of the maxillae, corrective surgery of the auricle, reparative surgery of the auricle, treatment of harelip, corrective surgery of the breast, reparative surgery of

the breast, and plastic surgery of other regions. As would be expected, particular attention is given to the technique of facial surgery.

The book is well printed and illustrated, appears to be fully documented, and is of interest as the fruit of twenty-five years of practice by a leading French exponent of the art of plastic surgery.

Notes on Books

In welcoming the first edition of E. B. SPAETH'S *Principles and Practice of Ophthalmic Surgery* attention was drawn to the fact that this is an exposition of the surgical pathology of the eye as well as a textbook on operative surgery, and that a number of procedures advocated by the author were not widely practised in this country. The new edition (Kimpton, 48s.) retains the character of the original text, and the individuality of the book is rather more obvious than before. It has now become an imposing tome, and, while little fault can be found with the exposition as a whole, there is still room, as was pointed out in our previous review, for the elimination of redundancy. Of topical interest are the excellent chapters on plastic surgery. This is a field to which the author has contributed extensively, and his guidance towards the principles underlying modern plastic surgery is of great help to procedures with which most ophthalmologists are relatively but little acquainted. The illustrations are well chosen, though more use could perhaps be made of sketches indicating steps to be followed. Such sketches are of greater help to the operating surgeon than photographs showing the initial and end stages seen in particular patients. In spite of minor defects the present volume is likely to establish itself as a standard work in English on the surgery of the eye.

The original edition of J. G. CROWTHER'S *British Scientists of the Nineteenth Century* came out in 1935 and contained descriptions of the discoveries and the life histories of Sir Humphry Davy, Michael Faraday, James Prescott Joule, Lord Kelvin (William Thomson), and James Clerk Maxwell. It was commended in these columns for the author's vivid character sketches and the very complete enumeration and description of the discoveries of the five physicists which formed the main part of his book. The work has now been republished in two small volumes of the sixpenny Pelican series. Vol. I comprises Davy, Faraday, and Joule; vol. II the lives of Kelvin and Clerk Maxwell, and also a life of William Henry Perkin, specially written for this edition. Perkin was the creator of modern chemical industry, which has so profoundly influenced the destiny of nations. It was in 1856 that Perkin began, at the age of 18, the systematic invention of new dyes from substances without dyeing properties. It led to the invention of new drugs, perfumes, flavouring matters, textiles, explosives, and other additions to human means. The industry he created was imitated in Germany and brought to such a pitch there that it has become the core of the scientific part of the German war effort. Mr. Crowther examines Perkin's work in relation to his own character and social environment, in order to throw light on why the growth of chemistry has been so different in Britain and Germany and to illustrate some of the scientific factors that have become an essential part in the power of modern nations.

To be faced with 320 pages on *Worry in Women* in close print on poor paper was daunting to the reviewer. But AMBER BLANCO WHITE early engages one's sympathy by her confession that the book has been extremely difficult to write. She hoped to help women to deal with their tendency to worry. First her book was too anecdotal; then too theoretical. This is the third draft. Unfortunately one has to own that it still attempts too much. Mrs. White shows her wide knowledge of women's mental processes, but the causes of illegitimate worry are inadequately differentiated from those of serious origin. She looks at worry in a sympathetic, friendly spirit through confessedly Freudian spectacles. Practical common sense based on psychological instruction is the method of help. Feelings of guilt and inferiority are faithfully dealt with; morality seems to be repre-

sented as purely human, and wisdom to be within the limits of self-knowledge. Worry connected with husbands and children is treated thoughtfully but, probably in an effort to meet too many cases, with confusing fullness. The book is a sincere effort to treat the disease of worrying; for greater accuracy of aim, suppression and subdivision are suggested. It is published by Gollancz at 12s. 6d.

The Year Book of the Royal Society of Tropical Medicine and Hygiene for the year 1942 has now been issued from Manson House, 26, Portland Place, W.1, at 5s. It gives full information about the work and personnel of the Society, which during the war has still managed to publish the usual six numbers of its *Transactions*. In view of war conditions and the number of Fellows on active service, it was decided to postpone the election, due this year, of a new Council and officers; and that the President, Sir Rickard Christophers, the vice-presidents, council, and officers elected in 1939 should be asked to remain in office for the time being.

In our notice of the second edition of Miss K. C. Clark's *Positioning in Radiography* (November 8, p. 654) we erroneously stated that the number of illustrations is the same as in the first edition. In all 125 new illustrations have been added, though this is rather disguised by the fact that Messrs. Ilford Ltd. have retained the original numbers, making the additional figures *a, b, c*, as the case might be.

Preparations and Appliances

A SELF-FITTING SLING

Miss M. M. BATE (a member of the St. John Ambulance Brigade No. 9 Nursing Division, and Instructor at two gas cleansing stations) writes:

The sling here described and illustrated has been designed and made with a view to its use primarily for cases of injury to the upper limb in gas-contaminated casualties. It is made of a strong soft cotton yarn, skilfully designed to take a limb comfortably, and at the same time allows free access to the skin for gas cleansing purposes. It will stand up to washing and boiling. The details of construction are as follows:

The "self-fitting sling" is made of cotton yarn, or other soft material which may be crocheted. It is hammock-shaped and in the form of a wide mesh, and is so constructed that it adapts itself to any position of the arm. This result is obtained because the centre part is made of the largest mesh, decreasing gradually towards the ends. A decrease in stitches at the edges, in the middle of the sling, in relation to the increase in the centre, brings about the snug fit which supports the arm and keeps it in position, and also causes the edges to be strengthened by what amounts to a double line when taut.

It is primarily intended for use in gas cleansing stations for those who, in addition to being contaminated, have received injuries necessitating the support of the upper limb. The sling can also take the place of a large or small arm sling or a St. John sling in circumstance of injury where no gas contamination exists. The special advantages are (1) simplicity, (2) speed of adjustment, and (3) the mesh allows the injured part to be cleansed with soap and water in contaminated cases while the sling is on.

The design has obtained a provisional patent. It is to be hoped that the sling could be widely adopted, as it is easy to make, cheap, and can be utilized in other ways than for gas cleansing stations.

SATURDAY DECEMBER 6 1941

ROUTE OF INFECTION IN POLIOMYELITIS

The occurrence of an outbreak of poliomyelitis in Berkshire, the closing of schools, and the barring of children from cinemas are all facts which serve to emphasize how little is actually known about the disease, despite the intensive studies of the past thirty years. Why should poliomyelitis be rare in Great Britain? It is common enough in the Scandinavian countries, in Canada and the U.S.A., and, at the other end of the world, in Australia. Is the disease transmitted as a droplet infection? If it is, then why should its greatest prevalence be in the summer and autumn months when other droplet infections are at their lowest ebb? Is the disease transmitted by infected food or water? If it is, then our efforts should be directed to a study of fingers, faeces, food, and flies, and to a discovery of possible carriers. If poliomyelitis is akin to dysentery or typhoid, it is curious that Egypt and the Middle East are untroubled by epidemics of the disease, despite the fact that the earliest indication of poliomyelitis is to be found in Egypt on a stela of the Nineteenth or Twentieth Dynasty, about 1300-1200 B.C.

An effort to solve some of these conundrums has now been made by Toomey.¹ By correlating pathological changes and clinical symptoms in man he attempts to reach definite conclusions about the portal of entry of the virus into the human body, and, as a corollary, to lay down the steps necessary to prevent the spread of the disease. Toomey's arguments may be briefly summarized. It is taken as axiomatic that the cerebral cortex is not a favourable site for either the development or preservation of the virus; nevertheless, as the name poliomyelitis (πολιός, grey) implies, the virus has an almost obligate affinity for the grey matter of the cord. Bodian and Howe,² in fact, suggest that the virus is not only neurotropic in that it has a predilection for nervous tissues, but is neuronotropic in that it has a selective affinity for, and probably is dependent for its growth upon, living nerve cells of certain types. To reach the nerve cells the virus must establish contact with axis cylinders by means of which it passes from the exterior of the body, from the skin or mucous membrane. In the skin, however, the non-medullated nerve endings are protected from the exterior by a thickened horny layer, with the result, as might be expected, that intact and untraumatized skin is experimentally a poor portal of entry, though when the virus is injected intradermally infection readily develops. A flap cut in the skin of an experimental animal, no less than the extraction of a tooth or the removal of a tonsil in man, provides a field where virus and non-medullated nerve endings can meet and hence where infection can occur.

There are, however, certain regions in the body where the same thing can take place apart from trauma—the olfactory mucosa, around the taste buds in the tongue, the tonsillo-pharyngeal area, the intestinal mucosa, and possibly the bladder wall and the respiratory tract. Can any of these portals of entry be correlated with the fact that in man the paralyses are usually segmental in type and in most cases involve the lumbar, cervical, and bulbar enlargements in the order named, pathological changes being practically restricted to these areas? Up to a short time ago attention was focused on the olfactory tract as the most important, if not the sole, portal of entry of the virus. It was always difficult, however, to explain the presence in man of extensive lesions in the lumbar and few or no changes in the bulbar and cervical enlargements if the virus entered by the olfactory mucosa. Entry by this portal fails also to explain the rarity of lesions in the thalamus, even in those who die with bulbar symptoms, or the lack of definite signs of involvement of the spino-thalamic tract, which carries pain and temperature sense fibres in the lateral column and touch and pressure sense fibres in the ventral branch. When in rhesus monkeys the first and thirteenth cranial nerves are disconnected from the brain and virus is injected intravenously the animals still develop the disease, thus showing that an intact olfactory tract is not essential for the production of poliomyelitis. Finally, in human post-mortem material there is no evidence of pathological involvement of the olfactory bulbs. Clinical and pathological evidence in man, as well as experimental evidence in monkeys, thus gives no support to the view that the olfactory mucosa is the normal portal of entry of the virus.

What evidence, on the other hand, can be brought forward in favour of the gastro-intestinal tract as the portal of entry, a view put forward as long ago as 1907 by Harbitz and Scheel?³ In the gastro-intestinal tract there is no thick epidermal layer, as there is in the skin, and virus should thus have no difficulty in coming into contact with non-medullated fibres of the sympathetic and parasympathetic nervous system, provided there is sufficient time for absorption. When the virus is placed in the intestine of the rhesus monkey poliomyelitis does not occur, probably because virus is swept through the intestine by rapid peristalsis. If, however, the intestines are mechanically dilated the disease is easily produced, the paralysis being segmental, as in man. This is presumably because the virus has time to come in contact with non-medullated nerves and to be absorbed by axis fibres. The exact route by which the virus passes from the intestine to the cord in man is, however, not quite clear: for Toomey it is by way of the sympathetic fibres and the somatic nerves of those segments lacking white rami communicantes: it would thus first reach the lumbar cord, and (as is well known) the lower extremities in man are usually first affected. With greater susceptibility on the part of the patient, or a more poisonous strain of virus, there might be spread along the sympathetic collateral chain to the other segments that lack white rami communicantes—in other words the cervical area. In this connexion Howe and Bodian⁴ have found that after transection of

¹ *J. Pediat.*, 1941, 19, 103.² *Johns Hopk. Hosp. Bull.*, 1941, 63, 58.³ *Deutsch. med. Wochs.*, 1907, 33, 1992.⁴ *Johns Hopk. Hosp. Bull.*, 1941, 63, 68.

the cord in monkeys the virus may pass from the cord via the sympathetic fibres to the paravertebral chains and, after ascending in them, re-enter the cord; or in the absence of intact sympathetic chains it may continue to the wall of the gut, where in Meissner's and Auerbach's plexuses it comes into contact with the pre-ganglionic fibres of the vagus and ascends to the brain. The isolation of virus from the coeliac ganglion of one patient with bulbar symptoms by Sabin and Ward,⁵ and from two other patients by Toomey, strongly suggests the sympathetic nerves as a route for infection; but the evidence is not entirely conclusive, for lesions in the coeliac ganglia of chimpanzees have been found in instances where the primary point of infection is known to have been the olfactory bulbs (Howe and Bodian⁶). Physiological considerations are thought by Toomey⁷ to suggest absorption from the alimentary tract, for the reflex changes seen in early cases of poliomyelitis in man are very like those in typhoid. Experimentally poliomyelitis can be transmitted to *Cercopithecus* monkeys by feeding, and has been produced in the chimpanzee by way of the gastro-intestinal tract, while in man the virus has been isolated from the faeces and in epidemic areas from the sewage. Epidemiologically Aycock and Eaton⁸ have shown that the peak of incidence of poliomyelitis occurs at the same time as that of typhoid. Further evidence of the similarity of poliomyelitis and typhoid is to be found in the isolation of poliomyelitis virus from flies caught in the neighbourhood of infected cases in Connecticut and Alabama by Paul, Trask, Bishop, Melnick, and Casey.⁹ The exact species in which the virus was present is uncertain, for the injections into monkeys were made with a mixed bag of greenbottle flies, *Lucilia sericata*, *L. caesar*, and *L. sylvorum*, together with the blow-fly *Phormia regina*, the house-fly *Musca domestica*, and a few *Muscina stabulans*, *Sarcophaga haemorrhoidalis*, *Ophyra leucostoma*, *Protocalliphora*, and *Stomoxys*. These findings thus confirm experiments made some years ago, when Flexner and Clark¹⁰ showed that house-flies contaminated artificially will carry the virus of poliomyelitis for several days, while occasional attempts to transmit the experimental disease by the stable-fly *Stomoxys calcitrans* were also successful. Thus the combined evidence suggests that the gastro-intestinal is the most common portal of entry of the poliomyelitis virus. Toomey, however, argues that the virus is not the only factor in the pathogenesis of poliomyelitis in man, but that certain toxins present in the gastro-intestinal tract act synergically with the virus.

Many workers, brought up on the theory that poliomyelitis arises by infection through the olfactory tract, may not agree with all Toomey's *obiter dicta*; nevertheless, experiments in which the olfactory or intracerebral areas have been used as portals of entry must obviously be repeated with the gastro-intestinal tract as point of entry. The question of the portal of entry is not purely academic: the evidence already available is sufficient to warrant an extension of the public health measures against poliomyelitis. In the past efforts to

control poliomyelitis as if it were a droplet infection have not been too successful; in the future it would be well to investigate and control each epidemic of the disease as if it were an outbreak of typhoid rather than of influenza.

REHABILITATION OF THE INJURED

A comprehensive national service for the rehabilitation of the injured must achieve two main objectives: first, it must ensure the maximum possible physical rehabilitation of every case; and, secondly, it must ensure that those who on reaching this stage are still unfit to return to their former jobs can be retrained and settled in some alternative work suited to their residual disabilities. Of these measures the first is undoubtedly of greater urgency and importance, for on its success or failure will depend the need for the second. This has been proved by the work of the Miners' Rehabilitation Centre at Berry Hill Hall in the Midland coalfield. This centre deals only with the most difficult and resistant cases from a number of organized fracture clinics over a very wide area, yet 95% of the patients are successfully reinstated in their industry, which is one of the hardest in the world, by physical rehabilitation alone.

The Ministry of Labour and National Service has recently announced a scheme for the retraining and settlement of disabled persons, so it is opportune to consider this in relation to the schemes already inaugurated by the Ministry of Health for the earlier treatment of these cases. Undoubtedly fractures constitute the most fertile single source of permanent disability; great importance hence attaches to the E.M.S. organization for dealing with these cases. The original scheme provided for eighteen orthopaedic centres to which certain difficult cases were to be transferred, but neglected to take into account the important fact that the treatment carried out before transfer is practicable usually determines the whole future of the case. For example, in compound fractures the most important single step in the whole treatment—excision of the wound, reduction, and closed plaster—must be carried out at the earliest possible moment. Under the original scheme there was plenty of organization for dealing with the complications resulting from bad initial treatment, but no organization for preventing such complications. It seemed almost as if, having prepared for the worst, we were determined not to interfere with a steady supply of clinical material.

This system has now been supplemented by one which provides a wide network of hospitals possessing the requisite specialized staff and equipment to deal with fractures, and distributed in such a way that every case should be assured of efficient primary treatment. Of these hospitals those in non-vulnerable areas (Class A) subsequently collect from those in adjacent vulnerable areas (Class B) all the longer-term cases, and it is therefore in these Class A fracture hospitals that the facilities for completion of physical rehabilitation must be developed. A great deal yet remains to be done in this direction; but if the scheme is made to work in practice as it appears on paper, the

⁵ J. Hyg., 1941, 51, 49.

⁶ Johns Hopk. Hosp. Bull., 1941, 69, 149.

⁷ Science, 1941, 93, 395.

⁸ J. Amer. med. Ass., 1911, 56, 1717.

orthopaedic centres should be relieved of a small army of patients suffering from the complications of inadequate primary treatment, and Mr. Bevin should be relieved of a small army of chronically disabled persons in need of retraining. But, however perfect any such organization may be, there will inevitably remain a small number who will require retraining, and the Ministry of Labour's scheme provides for these. It will be operated through local officials, attached to groups of hospitals. These officials will make contact with the patient towards the completion of his treatment, and by discussion with him and with the surgeon will arrange for a suitable course of retraining after his discharge.

The Ministry's existing schemes for training normal persons in various classes of munition work will be utilized, because much of this work is readily adaptable to disabled persons. In addition there will be special training centres for more difficult cases on the lines of the existing vocational training centres at Oswestry, Exeter, and Leatherhead, which did such valuable work for cripples in peacetime. All these training schemes will be carried out under medical supervision, and the trainees will receive adequate allowances during their period of training, which is expected in average cases to last about six months. So far as possible the training will be undertaken within daily travelling distance of the patient's own home, and this is a very important point. Many disabled persons will readily take advantage of a scheme which allows them to remain at home, but will think twice or even three times before they decide to go away into lodgings. With this in mind the Ministry has arranged for training to be undertaken in technical colleges and employers' works.

The present scheme is frankly regarded as being of an interim nature, and will be developed in the future according to experience. For the present the chief training will be for various war industries, but later on there is to be a resettlement of these persons into our permanent peacetime economy. This is a problem for the future. One of the greatest tragedies of the last war was the large army of unemployed and unemployable cripples who remained as a not always silent reproach to the politicians of those days. The two schemes discussed above show that the present Government has learned a lesson from its predecessors, and is determined that, for once, history shall not repeat itself.

WAR AND THE COMMON HEALTH: A PARADOX

Only three Presidents of the Society of Medical Officers of Health have hailed from north of the Tweed. The third of them, Sir Alexander Macgregor, medical officer of health for Glasgow, delivered his presidential address the other day. It was a comprehensive deliverance, surveying the whole field of public health service in wartime, from the standpoint of Glasgow experience but with applications to the whole of Great Britain. It is a mere commonplace now that the public health service has been subjected to immense strain: new demands have been made upon it; it has acquired previously unforeseen functions, it has widened its outlook and methods, and has gained new experience which will be of surpassing value in the post-war situation. The medical officer of health has had no release from his

normal duties, which indeed have acquired a new urgency from the war; to these have been added the oversight of the new emergency services, and, as though this were not enough, post-war problems are now knocking at the door of every town and city hall in the kingdom.

Sir Alexander Macgregor was not speaking only for the West of Scotland when he said that the health of the people had been better than was expected, in spite of the many influences which might have told to the contrary—new dispositions of population, overcrowding, and the depressing effect of the black-out, to mention only three. It is true that there have been certain movements of sickness and mortality—a wave of diphtheria, for example—but these, in Sir Alexander's opinion, owe little or nothing to the war. The increased incidence of pulmonary tuberculosis, which has been causing concern in Glasgow as well as in other places, is a different story. It is possible that with the entry of large numbers of young people into employment an infection which would have been resisted in normal times has gained the upper hand. But the sharp initial rise in Glasgow in 1940 slowed down in 1941. As for the feeding of the people, Sir Alexander expressed the hope that the Ministry of Food, regarded by many people as an infliction, may continue in being after the war as an essential health service. No doubt he was thinking of it not as exercising control over imports and traders but as a means of ensuring the ideal rationing—that is to say, making available the right kind of food for those who need it most, and, above all, educating the people in dietetics. He believes that the manner in which the food situation is being handled by Lord Woolton's Ministry is making a deep impression on the attitude of the people towards the common articles of diet. What he calls a "milk psychology" has been created by the National Milk Scheme. As a Scotsman he welcomes the return of porridge to favour (but how will that be affected by the recent cut in milk supplies?) and the demand for the nutritious herring. The position with regard to health in the schools is also reassuring. School children have lost none of the physical gain that has been registered in recent years, though standards of cleanliness are still too low. Infant life has suffered from the two cold spells of the early months of 1940 and of 1941, and from the whooping-cough epidemic of a year ago. Here again the war can hardly be indicted. It is otherwise with the considerable rise in the number of deaths due to premature birth. Many of these may be of psychological origin in the pregnant woman, owing to shock and anxiety arising out of the war.

It appears obvious from such a survey as Sir Alexander Macgregor, with the background of his sixteen years' experience as medical officer of health for Great Britain's second city, gave to his society that the war has accelerated progress in the field of public health—exactly the reverse of what a superficial observer would have predicted. Perhaps after all the evils and distempers from which we at present suffer have been released from Pandora's box, the treasure lying at the bottom will be found to be an advanced public health and social medicine.

PRESERVATIVES FOR STORED BLOOD

It has hitherto been customary to assess the value of any solution as a preservative for stored red cells by *in vitro* tests: changes in osmotic fragility of the erythrocytes and the rate at which spontaneous haemolysis occurs during storage have been usually accepted as satisfactory criteria of the effect of any preservative. Dr. P. L. Mollison and Miss I. M. Young in our current issue produce strong evidence which suggests that the *in vivo* survival of the erythrocytes of stored blood after transfusion cannot be pre-

dicted from such *in vitro* tests. The result of *in vitro* tests may, indeed, be completely fallacious. They studied *in vivo* survival of stored red cells by the differential agglutination method of Ashby.¹ In brief, this consists of the transfusion of cells of Group O to a recipient of Group A. After the transfusion the recipient's blood therefore contains two types of cells—O and A. The A cells can be removed with anti-A serum and the free O cells counted. The survival rate of the transfused O cells may be estimated by counting them at intervals after the transfusion. Using this method, Mollison and Young have tested eighteen different preservatives in a series of over 100 transfusions of stored blood, to which *in vitro* tests were also applied. The *in vitro* tests used were: (1) the degree of spontaneous haemolysis; (2) the increase in haemolysis after a standard amount of shaking with glass beads; (3) fragility to hypotonic saline. With a group of preservatives which contained no glucose—that is, heparinized blood, defibrinated blood, blood stored with I.H.T., with sodium citrate, and with citrate-sucrose and citrate-dextrin mixtures—the survival rate of red cells stored for less than one week was satisfactory. Subsequently deterioration was rapid. In general, blood containing glucose survives as well as fresh blood when stored for less than fourteen days. During the third week of storage there is progressive deterioration. The best survival rate was obtained with the Rous-Turner mixture, which contains 400 c.cm. of 3.8% sodium citrate, 1,000 c.cm. of 5.4% glucose, and only 600 c.cm. of blood. This considerable dilution, leading to a plasma of low protein content, is a practical point against the use of Rous-Turner preservative under conditions when stored blood is often converted to plasma. The glucose-citrate solution used by the Medical Research Council gives adequate survival up to fourteen days, and also provides plasma with a reasonable protein content. Certain preservatives shown to have excellent *in vitro* results had disastrous survival rates. For instance, though sucrose inhibits haemolysis during storage it gave a bad survival rate. The same was true of dextrin.

A further interesting result is recorded in this paper—namely, that changes in osmotic fragility may occur. When extremely fragile cells were transfused no increase in mean corpuscular fragility was observed in the recipient's blood or in the shape of the fragility curve. Further, when the fragile red cells were put into fresh plasma *in vitro* the mean corpuscular fragility reverted to normal. The most likely explanation of this reversal in osmotic fragility is that glucose is washed out of the cells when they are placed in a solution of relatively high tonicity at room temperature. This observation again emphasizes the importance of remembering that the red cell is an extraordinarily labile object, apt to change its size, shape, and characteristics rapidly. It must not be regarded, as is often done, as unchanging. It is clear from this interesting study that no preservative solution for red cells should be recommended until its effect upon the subsequent *in vivo* survival of the erythrocytes has been determined.

RADIUM THERAPY IN WARTIME

A pamphlet on air-raid precautions to be taken by holders and users of radium was recently issued by the Ministry of Home Security in conjunction with the Ministry of Health to county councils and county borough councils for circulation to those concerned.² The Commission wishes to re-emphasize that the object of the precautions (which are those it considers necessary) is not to restrict but to promote the use of radium under conditions of reasonable safety. It is an urgent necessity that radium

therapy should be resumed and increased by recognized centres throughout the country, so that all patients in need of this treatment can obtain it under safe conditions with the least possible delay. The Commission therefore hopes to hear from national and regional radium centres that they have now made arrangements to put into full use the whole of the national radium on loan to them. If any centre finds itself unable to do this, the Commission should be informed, so that the radium may be withdrawn and issued to other institutions where it may be needed. It has been decided that all national radium containers requiring return to the National Physical Laboratory, for repair or any other purpose, must be brought by a representative of the centre to the Commission office at Westminster Hospital, due notice having been given, as at present, to the National Physical Laboratory and the office secretary. Detailed instructions as to procedure have been given to the responsible authorities.

LUNGWORMS AND THE SWINE INFLUENZA VIRUS

When asked where flies go in the winter-time the biologist should be able to give a reasonably complete answer; the medical man, if asked where influenza viruses go when they are not producing influenza, would find it hard to know what to reply. Shope,¹ however, has now brought forward evidence to show at least where the swine influenza virus goes when it is not actually giving the pig influenza. In order to induce swine influenza it is necessary, it will be remembered, to inject the pig not only with the swine influenza virus but also with the bacillus *Haemophilus influenzae suis*. Of the two agents which thus act in concert to cause the clinical disease the bacterial component is capable, on injection, of eliciting an immune response that affords only partial protection against the disease. A swine influenza virus vaccine, on the other hand, confers a complete immunity to swine influenza. In the course of further experiments on the effect of multiple injections of *H. influenzae suis* in pigs a curious phenomenon came to light. Apparently normal pigs which had been given three injections of killed bacilli showed a mild febrile reaction exactly like that which follows infection with the swine influenza virus. After three injections of the living bacilli the pigs developed a disease exactly like that resulting from infection with both the components necessary to induce the clinical symptoms of typical swine influenza. The most likely explanation of the phenomenon seemed to be that the pigs, though apparently healthy and susceptible to swine influenza, harboured the virus in some unknown manner. Various experiments eventually showed that the swine lungworm can serve as an intermediate host in transmitting swine influenza virus to pigs. The virus is, however, present in a masked non-infective form in the lungworm, and to induce infection the virus must be rendered active by the application of a provocative stimulus to the swine it infests. Multiple intramuscular injections of *H. influenzae suis* furnish such a means of provoking infection. Swine influenza infections can be provoked in properly prepared swine during the autumn, winter, and spring. Although the phenomenon is not regularly reproducible, it occurs in well over half the experiments conducted in other seasons than the summer. Why the summer should be a refractory period is at present unexplained. The virus, it seems, can persist in its lungworm intermediate host for at least two years. Swine infected with swine influenza virus by way of the lungworm intermediate host show a more pronounced pneumonic process in the posterior lobes of the lungs than do animals infected intranasally with virus, but the situation of the worms providing the virus will

account for this. Occasionally, swine infested with lungworms carrying influenza virus fail to become clinically ill after injections of *H. influenzae suis*, but become immune instead. In these it is believed that lungworms containing the virus are localized outside the respiratory tract at the time of provocation.

The question naturally arises whether other viruses may not remain latent in parasitic worms. In a single experiment performed by Shope, swine lungworms failed to transmit hog cholera virus; but Stein, Lucker, Osteen, and Gochenour² have found that strongylus worms collected from horses suffering from infectious anaemia harbour this virus: the virus of infectious anaemia was not found in *Cylicostomes* or bots derived from infected horses. Whether worms play any part in the life-history of the virus of infectious anaemia of horses requires further investigation; so far the virus has not been found in either eggs or larvae in the faeces of infected horses.

CO-OPERATIVE THERAPEUTIC RESEARCH

A group of leading manufacturers of medicinal products in this country has formed an organization for the more effective prosecution of research in their industry. It will be known as the Therapeutic Research Corporation of Great Britain Ltd., and the five constituent founder companies are Boots Pure Drug Company, Ltd., the British Drug Houses Ltd., Glaxo Laboratories Ltd., May and Baker Ltd., and the Wellcome Foundation Ltd. The registered offices for the time being are 183, Euston Road, London, N.W.1. This is not a merger or amalgamation of the companies concerned; each of them retains complete freedom of action in its special fields, and, while contributing to a new research pool, forfeits none of its special characteristics. Plans for research will be drawn up from time to time by a research panel comprising the heads of research from the several constituent companies and having power to co-opt or consult with other scientific workers when special problems arise. Products evolved as a result of research thus sponsored will be marketed and sold by the constituent companies under a common name, and in this connexion we note with approval that the Corporation undertakes to assist wherever practicable in simplifying the nomenclature of new medicinal substances. The directors of this organization are Lord Trent, chairman and managing director of Boots, Mr. C. A. Hill, chairman and managing director of British Drug Houses, Mr. H. Jephcott, managing director of Glaxo Laboratories, Mr. T. B. Maxwell, managing director of May and Baker, and Mr. T. R. G. Bennett, chairman and managing director of the Wellcome Foundation.

PREVENTION OF LIVER DAMAGE

The interventions of the surgeon are, in one respect at least, more damaging than those of a malevolent enemy: the latter affect healthy men; but the patient facing operation is, physiologically speaking, seldom at its best, either by reason of his disease or because of those antecedent conditions which produced the infirmity. Although seldom as dramatic as surgical intervention, the administration of drugs may be equally hazardous, and here, too, the risk is often increased by the poor health of the subject. Much work has been done with the object of improving this state of affairs. But whereas assessment of the effects of treatment in man is often difficult, that of the benefits of pre-therapy—that is, treatment preparatory to treatment—

is doubly so, for the simple reason that in most patients therapeutic agents are seldom used in strengths sufficient to cause damage. Recourse has therefore been made to animal experiment. By this means, for instance, we have learnt almost all we know of the protection of the liver against such drugs as chloroform and arsphenamine. It is now well recognized, through the work of Ravdin and his associates³ and Miller and Whipple,⁴ that a high protein intake affords even better protection than carbohydrate, and, conversely, that depletion of body protein predisposes to liver damage by these drugs. Analysing this protective action of protein further, the latter authors³ found that methionine and, to a lesser degree, cysteine gave a very high degree of protection, whereas other non-sulphur-containing amino-acids did not. The sulphydryl group of these compounds is commonly conjugated by the liver with certain foreign substances, which are thereby "detoxified" and excreted as mercapturic acid: such, Miller and Whipple suggest, may be its action here (though in preliminary experiments no such compound has been found).

A further interesting discovery is the protective effect of the injection of various diverse substances whose only common action is that of producing an inflammatory reaction. Ravdin and his associates⁴ believe that this is attributable to the increased breakdown of tissue protein which occurs with any inflammatory process. The biochemical aspects of inflammation are too little understood for it to be certain how much of this proteolysis is generalized (if any), and how much is due to the local source entirely. Menkin⁵ suggests that local inflammatory proteolysis is responsible for the enhanced gluconeogenesis seen in diabetic subjects with superadded infection. It would be rashly teleological to conclude that this protective action of inflammatory proteolysis was evolved to combat the evil effects of chloroform addiction in the starved. It seems, however, at least possible that there may be other and more natural processes—for example, burns—which produce similar effects on the liver and in which this protective action may be concerned. The natural objection to the comparison of such animal experiments with similar therapeutic trauma in man is that the animal is previously healthy, whereas the patient is not; a better comparison is that pointed out above between the subjects of surgical trauma and those of enemy action. The results might, therefore, be expected to be more favourable in the animal than in the human recipient of drugs. However, from the work discussed above it is possible that the reverse may often be true, and that the subjects with infection may be in a more favourable condition to withstand further insults than those without.

A general meeting of Fellows of the Royal Society of Medicine will be held on Friday, December 12, at 2.30 p.m., when Sir Almoth Wright will read a paper on "The Need for Abandoning Much in Immunology that has been Accepted as True."

The next annual general meeting of the British Orthopaedic Association will take place in Oxford on January 2 and 3, 1942. The scientific sessions will be held in the lecture theatre of the Department of Human Anatomy at 9.30 a.m. on both days. The programme includes an address by the president, Prof. T. P. McMurray, on "Conservatism in Orthopaedic Surgery," and a paper by Prof. Philip Wilson (New York) on "Arthroplasty."

IMPRESSIONS OF A REGIMENTAL MEDICAL OFFICER

BY

R. C. L'E. BURGESS, M.B.

After reading Major J. T. Robinson's article on the army medical officer (*Journal*, October 18, p. 555), it seems opportune to put on record certain impressions gained during two years as regimental medical officer to a training depot.

Having worked for twelve years in a mixed general practice, the first point to strike me forcibly was the similarity between the men attending daily sick parade and those attending the civilian surgery; the only real difference was that a soldier has to attend for minor ailments which he would not dream of reporting to his civilian doctor. This is not the soldier's fault, but is rendered necessary because of the rule which insists that no man may be excused all or part of his drills without a supporting medical certificate. It is quite unnecessary, and often not desirable, that every man who reports sick should be given a thorough physical examination. Any practitioner who has been used to busy surgeries will easily pick out those who require a detailed examination and those who can rapidly be dismissed with a placebo or, if necessary, an admonition.

An introductory address was always given to each new intake of recruits, in the course of which it was emphasized that the R.M.O. was in point of fact their panel doctor. This was invariably appreciated by the audience, 99% of whom were panel patients in civil life, and had had in the main a fair deal from their doctor. A brief description of the methods by which a soldier could see his M.O. was then given, and in order to overcome the somewhat stilted atmosphere of the daily sick parade—for which the sick were first paraded at the regimental office, then marched up to the medical inspection hut or room by the sick and defaulters orderly (an unfortunate combination of terms)—it was suggested that whenever possible men should report sick after duty. An informal sick parade was held between 5.30 and 6 p.m.; this proved very helpful in getting to know the men, and also in discovering and segregating those who had started a feverish condition during the day and who in the normal course of events would not have reported sick till the morning, thereby being in close contact with their fellow soldiers during what is probably the period of greatest infectivity.

A recruit probably makes more appearances on sick parade during his first month in the Army than during the next twelve months. This is partly due to change of environment and to the breaking in of new boots, with accompanying sore feet, but more often it is due to the results of inoculations, particularly primary vaccinations.

A satisfactory contact with the men having been made, the R.M.O. should endeavour to be equally successful in his dealings with the Commanding Officer. One point which no R.M.O. should ever forget is that he is an expert employed in an advisory capacity, and that once he has convinced his C.O. that his medical knowledge and judgment are sound, it should rarely be necessary for the A.D.M.S. to exercise more than a benevolent supervision over the medical arrangements of the regiment.

Diagnoses on sick reports should so far as possible be couched in simple language. Claw-foot and crabs mean much more to the lay mind than *pes cavus* or *pediculosis pubis*.

All cases of sickness having a direct connexion with the cooking or the sanitary arrangements of the regiment should be investigated at once; for any C.O. who notices that several cases of diarrhoea are recorded on the sick report will make immediate inquiry of the M.O., and it is obviously to the credit of the latter if he has a satisfactory answer ready.

Functional cases require a considerable amount of time and patience, and it is important that every case of neurosis should be thoroughly investigated by the R.M.O. before being sent to the psychiatrist. These cases may be divided into the following groups:

1. *Dull and Backward*.—These are usually straightforward cases; the common symptoms of headache and insomnia are brought about largely because recruits of dull mentality are unable to assimilate new technical details. These invariably obtain a C— in the F.H.3 educational test.

2. *Anxiety Neurosis and Hysteria*.—Some of these patients are dull, and the abrupt change in their lives has upset their mental balance. Often this upset is temporary, and they rapidly become normal on return to their homes and to civil employment. Others become unbalanced because of personal reasons—for example, dislike of a particular job, getting at cross-purposes with a superior, and often domestic trouble at home. It is very necessary for the M.O. to gain the confidence of these men, for it is not easy to get a soldier to tell of his unhappy personal difficulties.

There is a third group, fortunately a small one, of men who seem determined not to soldier, and ultimately it is necessary for the medical profession to decide whether these are psychopathic cases or not. In the few cases of this type that passed through my hands I was not always convinced that the recommendation for discharge made by the psychiatrist was the correct one. I have attended several informal talks between the psychiatrist and the commanding officer of a training regiment, and I know that the arguments raised by the psychiatrist have failed to convince the lay mind. It would be preferable if cases recommended for discharge were transferred to a psychological depot, where they could be kept under continuous observation before finally being boarded out of the Army.

Conclusions

A medical officer should not be posted to a regiment unless he has spent at least six months in general practice.

The preliminary R.A.M.C. course should be followed by a fortnight's duty under an experienced R.M.O., possibly in a training camp. This would help the newly joined medical officer to put into practice the theoretical knowledge he has learnt at the depot.

It is important that the R.M.O. should be a good mixer, and be respected by both officers and men. He should be fair and unbiased in his approach to the various problems that will arise.

Just as in civil life some doctors are quite unsuited to general practice, so in the R.A.M.C. there are men unsuited to regimental practice. These should, if possible, be sorted out in the initial training and be sent to other branches of the Service.

It is recognized by many A.D.M.S. that on the efficiency of the R.M.O.s depends the health of their Divisions, and it seems a pity that it is not possible for proved experts in regimental medical duties to be granted increased responsibilities in their own sphere. The present unit of 800 to 1,000 men scarcely provides enough work for an experienced M.O., and he could look after double that number without being overworked.

The reception stations in this country give an increased chance for an R.M.O. to carry out better medical work, and every facility should be given to enable medical officers to do duty in them.

Short spells in hospital would be welcomed by all M.O.s, as would postgraduate courses arranged in conjunction with the various teaching hospitals.

According to the *Deutsche Medizinische Wochenschrift* (March 28, 1941), a new order for combating trachoma in the Eastern Territories (Poland) has been issued by the Governor-General. The order stresses the responsibility of the patient, his parent or guardian, and the doctor with regard to the disease in order to impress on the population the necessity for treating it. In co-operation with the Trachoma Research Institute in Cracow, the Children's Trachoma Hospital in Witkowicz, and a network of mobile units now to be put into operation, a start has been made to combat this disease. A special trachoma hospital has been equipped in Litzmannstadt. It is calculated that there are about 100,000 cases of trachoma in Poland.

LOUSE-BORNE TYPHUS FEVER

As briefly announced last week, the Ministry of Health has issued a note on this subject (Memo. 252/Med.) summarizing the principal facts and giving guidance on diagnosis and administrative control. The existence of louse-borne typhus fever in Europe and North Africa at the present time makes it advisable to take precautions in case the disease should reach this country through refugees, prisoners of war, or returned travellers. This memorandum deals only with the louse-borne type of typhus as it may occur in this country, but it must not be forgotten that the varieties of typhus fever carried by the tick and the flea have in the past been introduced into Great Britain. The form of typhus under consideration is carried by body lice and probably by head lice. It may occur with typical severity in a perfectly well-nourished person; mild cases may occur and are liable to be missed.

Clinical Features

Louse-borne typhus fever is an acute infectious disease lasting from twelve to sixteen days. It is characterized by a general maculo-papular rash which may become haemorrhagic and which is invariably absent from the face. Toxaemia and nervous manifestations are severe. The incubation period is usually between eight and twelve days and most commonly about ten; exceptionally it may range between five and twenty-three days. The onset is sudden, but may be preceded by malaise. Common initial symptoms are rigors, headache, pain in the limbs and back, vomiting, and epistaxis. The temperature generally rises rapidly to 103° F. or more. The patient soon develops a dull and heavy expression with flushed and congested face, swollen eyelids, and injected conjunctivae. Delirium begins very early and bronchitis is common. The tongue is furred and later tremulous, with limited power of protrusion. The patient gradually drifts into the "typhoid state," which is fully established between the third and fifth days. There may be either maniacal manifestations or mental torpor. Bronchopneumonia is a common complication. Cardiac dilatation and weakness are almost invariable and heart failure is frequent.

The rash begins on the fourth or fifth day as small red papules in the axillae, on the abdomen and chest and back, later spreading to the extremities. For a day or two the papules fade on pressure, after which they fail to do so and become dull red. They may resemble closely the eruption of typhoid fever, but in general are more numerous, and fresh crops do not appear. In some cases subcuticular lesions, which may be as large as a shilling, appear between the papules and give the effect of marbling. Ecchymoses may form upon the skin of dependent parts. In children especially the rash may be absent or may be confined to a few papules on the chest. When haemorrhagic it closely mimics that of haemorrhagic small-pox, and may be accompanied by haematemesis, haematuria, and melæna.

The temperature, after its rapid rise, remains fairly steady throughout the illness, begins to fall about the twelfth day, and returns to normal by a rapid lysis. Though some patients remain in torpor throughout, others go through a phase of nervous excitation lasting some days. The patient then either passes into a "typhoid state" or dies. The special features of this state in typhus are nightmare dreams and a tendency for the tongue to shrivel, become nearly black, tremulous, and incapable of protrusion. In the "typhoid state" the patient may succumb, or he may rapidly pass into the stage of defervescence.

Diagnosis of Typhus

Clinically the diagnosis rests on the sudden onset with high temperature; the occurrence on the fourth or fifth day of the characteristic rash, typically absent from the face; and the striking mental condition.

About the end of the first week, and often earlier, the patient's serum develops the power of agglutinating the so-called Proteus X strains (Weil-Felix reaction). Samples of blood serum should be sent (1) in the London area—to any

sector pathologist of the Emergency Medical Service; (2) outside the London area—to any laboratory of the Emergency Public Health Laboratory Service, or to the bacteriological laboratory of the nearest university.

In the matter of differential diagnosis, fevers of the enteric group can be eliminated by the results of blood culture, cultures from the faeces and urine, and agglutination tests; cerebro-spinal fever may be very difficult to distinguish from typhus clinically, and reliance has to be placed on the results of examination of the cerebrospinal fluid and the Weil-Felix reaction; encephalitis may be distinguished from typhus by the gradual onset, absence of rash, the paralysis, and the absence of the Weil-Felix reaction; the prodromal rashes of small-pox may resemble those of typhus, and for some time the differential diagnosis may be difficult.

Administrative Control

Typhus fever is compulsorily notifiable to the M.O.H., who must report every case immediately to the Ministry of Health. The probability being that the disease would first be introduced into the larger aggregations of population, a number of the principal towns have been asked to organize teams for dealing with an outbreak, the personnel being provided with protective clothing and offered preventive inoculation. An illustrated description of a type of protective clothing found valuable in practice is appended to the memorandum. In view of the difficulty of diagnosis the M.O.H. is advised to arrange for the services of a medical officer conversant with the disease, resort being made to the medical staff of the Ministry of Health, or, in London, to that of the L.C.C. On application to the Ministry a mobile team from the Harvard Field Hospital Unit of the American Red Cross will be available for help in diagnosis and control in any part of England and Wales. The M.O.H. should without delay go into the question of providing hospital accommodation for cases of typhus. During the admission of a patient to hospital the staff engaged are particularly exposed to the danger of contracting the disease. Precise details are given on this important matter so that all lice may be destroyed. A special ward must be set aside for typhus patients and accommodation provided for the staff at risk.

Every effort must be made to trace the origin of the infection, and all persons who may have been exposed to risk must be freed from lice and kept under surveillance for three weeks. It may be necessary to delouse heavily infested persons a second time after an interval of ten days, to ensure the destruction of lice hatched from eggs that have survived the first delousing. Lastly, where the possibility of typhus exists every effort should be made to lessen the amount of louse infestation among the population generally. Apart from known contacts a vigorous campaign of cleaning-up of infested persons should at once be undertaken by the health authority. The powers with regard to disinfection are set out in an appendix to the memorandum.

GALLANTRY IN CIVIL DEFENCE

The award of the M.B.E. (Civil Division) to Dr. LESLIE FREDERICK WILSON, medical officer, Civil Defence First Aid Post Service, Kingston-upon-Hull, is announced in a *Supplement* to the *London Gazette* dated November 21. The announcement reads as follows: "Dr. Wilson has spared no pains in training the staff of his first-aid post, and the high standard of duty maintained by them has been largely due to his splendid example. On one occasion, when his post was isolated by fires and blocked roads, Dr. Wilson improvised temporary hospital accommodation for a number of seriously wounded patients and treated them until they could be removed by ambulance the following day. His coolness and devotion to duty during heavy raids have inspired all with whom he has come in contact."

Dr. KATHLEEN EVELYN SLANEY (Mrs. William Bullock), medical officer, Civil Defence First Aid Post Service, Southampton, has been commended for brave conduct in civil defence.

HERMAPHRODITISM: A HISTORICAL APPROACH

VICARY LECTURE BY DR. CAWADIAS

The Thomas Vicary Lecture of the Royal College of Surgeons of England was delivered before the President and Council on November 26 by Dr. A. P. CAWADIAS, whose subject was "Hermaphroditism."

Beginning with a definition of terms, Dr. Cawadias said that hermaphroditism should be taken as synonymous with intersexualism. It was a constitutional condition, or disease, characterized by the presence of male and female features in the same individual. There were three classes of hermaphrodites or intersexual beings: (1) the male hermaphrodite, the feminized man, in whom the male sex predominated; (2) the female hermaphrodite, the virilized woman, in whom the female sex predominated; and (3) the complete hermaphrodite or bisexual being, with complete sexual organs, both male and female. The textbooks notwithstanding, this last condition did not exist in humans.

The Greeks and Earlier

The ancient Eastern peoples, the Assyrians and others, imagined a bisexual deity or perfect being, a mystical image through which they tried to solve the problem of the sexes and the phenomenon of fertility. The cult of bisexual deities was taken over by the Greeks, whose bisexual deity was Hermaphroditus, but between the Greek god type of grace and charm, the harmonious blending of feminine beauty and adolescent virility, and the colossal, ugly, terrifying Oriental bisexual deities there was an immense difference.

It was during the Hellenic period that the really scientific view of human intersex began to be formed. The Greeks regarded the human being as a whole, a biological unit reacting to its environment. They observed accurately, reasoned close to the facts, and rejected all mystical and supernatural explanations. The ancient Greek physicians gave the first description of the two great classes of intersexualism. Hippocrates described both androgynoidism, or male intersex, in his "Disease of the Scyths"—what was known to-day as eunuchoid feminism—and gynandroidism, or female intersex, in his "Epidemics," and studied what was now described as the Cushing syndrome. The Greeks also described incomplete forms, *formes frustes*, of intersexualism. Aristotle pointed out the feminine nature of hypospadias, saying of such patients that they seemed to have the nature of man and woman at the same time. The male intersexualism of the Scyths was attributed by Hippocrates to the destruction of the semen through various diseases due to excessive horse-riding and their ill-considered treatment. For female intersexualism Hippocrates accepted the predominant role of ovarian dysfunction, and wrote, "We had the impression that if we could bring back the menstruation the symptoms would retrocede." Intersexualism was considered by the Greeks as a disease, a natural phenomenon, not a manifestation of divine wrath or a fitting indication for the cruelty shown by the Romans or at the Renaissance.

Succeeded by the Dark Ages

After the brilliant Greek period came the "period of fables," the dark ages of the history of intersex, beginning with Pliny in the first century, but continuing until the end of the eighteenth. Instead of accurate observations the physicians accepted tales in a remarkably uncritical spirit and persisted in superstition. The authors of this period described females turning into males; they did not accept the transformation of males into females, believing Nature to be progressive, from the imperfect to the perfect, from the female to the male. Ambroise Paré, a great surgeon but just as credulous as his contemporaries, reported the case of a "girl" who at the age of 15, on jumping over a stream, discovered to her horror male genital organs appearing at her perineum, no doubt to be explained as a case of cryptorchidism.

The greatest error of the physicians of this period was the notion of complete hermaphroditism among human beings. Some of the physicians who followed Pliny pretended to have seen such beings. In the works of Arnaud, a French surgeon established in London in the eighteenth century, there was an

account of two hermaphrodites of Valencia who married each other and both became pregnant through mutual ministrations. These physicians even believed in bisexual beings capable of self-fertilization, of which there was an echo in the theory of Langerhans, who explained the genesis of testicular teratomata by postulating that an isolated ovarian element became fertilized in the testicle.

In this period hermaphrodites were maltreated as expressions of divine anger. Not only the monsters but their parents were put to death, and that as late as the seventeenth century. Even when superstition began to wane, cruelty persisted. Hermaphrodites were allowed to choose their own sex, or a sex was imposed upon them, but to that they had to adhere and were punished terribly if they used the prerogatives of a sex which was not theirs.

The Mechanistic Physiological Period

The lecturer next came to the period which, although it began with Sydenham and Harvey, centred principally in the nineteenth century. The first clinical advance in this period was the description of the two genuine classes of intersexes as introduced into science by the Greeks. This fuller and more accurate clinical study was rendered possible by John Hunter and later by Charles Darwin in their conception of primary and secondary characters, the former comprising the organs effecting reproduction, and the latter the other features characterizing sex but not involved in reproduction. Dr. Cawadias himself gave a clinical grouping of sexual features: gonadal, genital, morphological, mental, and vocal.

A second line of advance in clinical knowledge was the isolation and description of incomplete forms, *formes frustes*, of intersexualism. Masochism and travestism—the latter, in the male, a love of feminine dress and adornment—had been so described, as had certain cases of male homosexuality, and there were similar *formes frustes* in female intersexualism, a female sadistic form, and so on. The third and most recent advance in clinical study of the intersex in this period related to physiopathological forms, of which adrenal gynandroidism—a female intersexualism depending on hyperfunction or dysfunction of the adrenal cortex—was the best known.

Although this period marked distinct progress, it fell short of the Hellenic period by its acceptance of complete hermaphroditism. Klebs, who was mainly responsible for the propagation of this erroneous conception, maintained the existence of complete hermaphroditism on the ground that some individuals possessed both ovary and testicle. In all cases of "complete" hermaphroditism described even to-day the testis or the ovary was rudimentary and not functioning. Bisexualism could not be accepted on such slender evidence. Was there a normal woman who did not possess in her ovarian medulla testicular rudiments, or a normal woman who did not secrete testosterone? According to Klebs's criterion all normal women should be considered true hermaphrodites.

The lecturer next traced the rise of the study of the endocrine mechanism of intersexualism, especially through the painstaking work which began with Brown-Séquard, demonstrating the masculinizing influence of the testis through its hormone, testosterone, and the feminizing influence of the ovary through its oestrogenic hormone. Subsequent work had shown the masculinizing influence of other endocrine glands, mainly of the adrenal cortex, and the feminizing influence of the thyroid. Intersex had been shown to originate in a disturbance of balance between the opposing hormones. Speaking of endocrinotherapy in this sphere Dr. Cawadias said: "I know of no fact more capable of increasing our faith in internal medicine than the complete transformation of repulsively feminized boys into normal virile adolescents, thanks to a few hormonal injections, or the change into beautiful and complete womanhood of girls with hairy faces and bodies and thick and acne-ridden skin, thanks to oestrogenic hormone therapy." But these almost magical results certainly did not justify the orgy of glandular injections given at random, often by men ignorant of the complicated physiology of the internal secretions.

The Biological Period

Coming to the contemporary period of medicine, which he described as the biological, Dr. Cawadias said that it was

characterized by the consideration of the living being as an integrated unit. The biological thinking of Hunter and Darwin had been carried on by such physiologists as Gaskell, Sherrington, Haldane, and the "clinicians of the whole man," maintaining in medicine the Hippocratic spirit. The development of sex was now better understood, and therefore disturbances in that development resulting in intersex became clearer. It was shown how sometimes, in the normal mechanism of sex development, the sexoformic impulse was deflected at a certain stage, and development then continued according to the opposite sex. This deflection could occur at various phases; the earlier it occurred the fewer organs differentiated, and therefore the more marked was the intersex. It proceeded from two groups of factors: hereditary weakness of the genetic impulse and factors of environment, the latter including education, imitation, and social milieu.

Sex was not a fixed feature; it was the result of an evolution, which continued. The lower beings remained at the stage of asexualism. Later sexual characters appeared, but coexisted in the same being (namely, plants and some lower animals); later still the sexes separated, and complete unisexuality could not be conceived at this, the human, stage of evolution.

In passing, the lecturer noted one differentiation between the sexes. Feminism in men—for example, in the male castrate—was regarded as a retrogression, but certain male features acquired by women were regarded as not abnormal but as perfecting the woman. He instanced Lady Hester Stanhope, the niece of William Pitt, a mild adrenal gynandroid, whose features and build were masculine, and whose courage, behaviour, and domineering tendencies were traits associated with the male sex, and yet she was admired, and had some sentimental and even physical adventures.

The Basis of Sex

The ovary and testis were not the basis of sex, but merely manifestations or results of the initial genetic sexoformic impulse, which in human beings was either male or female and never bisexual. A female was not the appendage of her ovaries, to use Virchow's phrase, but had ovaries because she was female. A male was not male because he had testes; he had testes because he was male. There was neither absolute male nor absolute female. Every male had more or less latent female features, and vice versa. Intensification of this normal intersexualism characterized the disease hermaphroditism, and all degrees were encountered.

As intersexualism was biologically a disease of the whole individual, not merely a disease of a particular endocrine gland, any treatment must be directed to the whole constitution. Had we any right to punish an individual who showed the homosexual form of intersexualism? Theoretically we had no such right. A male homosexual of intersexual origin was in fact an intersex who wanted to be a female. On the other hand, a homosexual was a focus of infection. Such a boy at school infected others, causing sex reversal through psychological factors, and handicapping them for life. The duty of society to such persons was to cure them or to prevent them from harming others.

Finally Dr. Cawadias touched on adrenal virilism, a special problem by itself. When it was due to a tumour, the indication for operation was the tumour, not the intersexual state. When it arose as an adrenocortical hyperplasia the problem was more complex. In adult cases no demasculinizing adrenalectomy should be performed if the patient wished to remain male. But the principle of sex choice should not be pushed so far as to withhold adrenalectomy in infantile cases of adrenal virilism, for the results of the operation were so brilliant that it was not justifiable to risk for these subjects the persistence of an intersexual state which, notwithstanding the predominance of one sex, was always a handicap.

HOSPITALS IN THE POST-WAR WORLD

INTERNATIONAL CONFERENCE IN LONDON

An international gathering filled the Great Hall of the British Medical Association House in London on November 25 when a conference was summoned by the United Kingdom Council of the International Hospital Association to consider the position of hospitals the world over at the dawn of peace. King Haakon of Norway, the Grand-Duchess of Luxemburg, and Dr. Benes, lately President of Czechoslovakia, attended, together with the Prime Minister of the Netherlands, the Belgian Ambassador, the Ministers of Norway, Venezuela, and Colombia, and official or other representatives of Poland, Yugoslavia, Greece, Palestine, Iraq, Egypt, Abyssinia, India, and China. The British Red Cross and the St. John Ambulance Association, the American Red Cross, and the Czech and the Netherlands Red Cross sent representatives, and there was a representative of the Free French Medical Corps. The Agents-General of several Australian States were present, as well as Sir Earle Page, the envoy of the Australian Government.

The Minister of Health (Mr. Ernest Brown) and the Secretary of State for Scotland (Mr. T. Johnston) attended, as did the Chief Medical Officer (Sir Wilson Jameson) and several officers of the Ministry, the President of the Royal College of Surgeons (Sir Alfred Webb-Johnson), the Chairman of Council of the British Medical Association (Mr. H. S. Souttar), and the representatives of many other bodies concerned with medicine, hospital administration, and social welfare.

Mr. W. McADAM ECCLES, chairman of the United Kingdom Council, presided over this assembly. At the outset a message was sent to the King, expressing gratitude for the interest he and the Queen have taken in the work of hospitals and the hope that with the swift coming of peace there may be freedom to continue and foster the healing art in every hospital in the world. Before the conference ended a gracious reply was received. A cable of greeting was also sent to the President of the International Association, Dr. MacEachern of Chicago.

International Hospital Collaboration

Dr. A. T. JURASZ, dean of the Polish Medical Faculty in the University of Edinburgh, opened a debate on the collaboration which must follow the war, a collaboration which must extend to all nations prepared to work together on a basis of honesty and friendliness. He suggested a greater interchange of personnel, both lay and medical; a six-months residence in the larger hospitals for graduates of different countries on a principle of international exchange, and an extension of post-graduate teaching. Prof. J. LOEWY (Czechoslovakia) followed with the suggestion for a "Health Union" among European countries, the basis of which would be the curative resources of each country, such as mountain sunshine or medicinal springs, and the distribution of patients without regard to national boundaries. Dr. GEORGE H. H. WOO (China) repeated the description of recent hospital progress in China which he gave to the China Institute the other day. Dr. KARL EVANG (Norwegian Minister of Social Welfare) said that in his country of three million inhabitants there was one hospital bed to every hundred of population. He believed that after the war the same system of hospital provision, based on sickness insurance, would continue. Dr. E. J. BIGWOOD (chairman of the Belgian Commission for the Study of Post-war Conditions) said that the Governments of the Allied countries at present in London had already considered a plan of action, both for immediate relief after the war and also for long-term development.

Hospitals in English-speaking Countries

Mr. McADAM ECCLES introduced a discussion on the special problems of English-speaking countries. It was not too early, he said, to consider problems that would arise as soon as peace was declared. He suggested that in any area the total number of beds required for in-patient treatment and the expected number of out-patients should be computed, the approximate annual cost per bed and per out-patient ascertained, allowance being made for some kind of sinking fund for the purchase of

The Ministry of Health has now issued in Circular 2395B the promised list of special clinics outside the Emergency Hospital Scheme which are to function as additional Fracture Clinics "C" (*Journal*, August 23, p. 290). Instructions on the method of referring cases to these clinics are being sent to all hospitals in the E.M.S.

new equipment and future rebuilding, and then on the basis of this annual budget it would be possible to announce the amount necessary from the local community for the support of their hospitals, and he did not doubt that the money would be afforded voluntarily.

Mr. H. S. SOUTTAR referred to the sweeping away of divisions between classes of hospitals. He had been a member of the staff of a voluntary hospital, but at present he was taking charge of an L.C.C. hospital under the control of the Ministry of Health. He referred to the work of the Medical Planning Commission as a kind of "Brains Trust" to determine the character of the after-war service, but, of course, the International Hospital Association, along its own lines, had a still wider purview.

Voluntaryism and State Aid

Lord GIFFORD, who has been associated with a hospital in Sydney, said that that hospital preserved its voluntary character although 60% of its income came from the State. More than half its board were State-appointed, but once they took their seats they were indistinguishable from other members. Voluntary hospitals would ask a great deal more aid from the State, and yet he believed that they could preserve their democratic character. Sir EARLE PAGE also said that in Australia they had endeavoured to incorporate the voluntary system with the maximum amount of State aid. Sir WILLIAM GOSCHEN (London Hospital) spoke of the need for a scheme which would bring the voluntary and municipal hospitals together. Mr. CARUS WILSON (St. Bartholomew's) said that the doubts which had been expressed as to the survival of voluntary hospitals after the war were also expressed during the last war, but voluntary hospitals continued then, and they would continue now. But they must look to such organizations as the Hospital Saving Association for augmentation of their income.

Among other speakers were representatives of the British Dental Association and the Royal College of Nursing, and the discussion was closed by Dr. ANDREW DAVIDSON (Chief Medical Officer for Scotland), who said that although the Committee on Scottish Health Services found a shortage of 3,600 beds, this had been more than made up by the Emergency Hospital Service. There was also now available for the first time in Scotland a comprehensive orthopaedic scheme.

E.M.S. Hospitals

Mr. ERNEST BROWN, Minister of Health, mentioned the close relation between Great Britain and the United States in connexion with the Emergency Medical Service. The U.S.A. not only had given material help but had lent medical and nursing personnel. The E.M.S. was not designed as a pattern for future development, but it had nevertheless proved a very useful experimental ground from which lessons of long-term value had been learned. It was organized to cope with the expected casualties of war, but in practice it had assumed a shape which made possible the adaptation to war needs of all kinds of existing hospitals and services. It had yielded experience with regard to the relation of hospitals one to another which would greatly influence the peacetime situation.

A HOMESTEAD SCHEME FOR MOTHERS AND CHILDREN

The family unit is the first casualty in war. If the nucleus of the State is the family—the living unity of father, mother, and children—then by some means the family should be enabled to maintain its status and fulfil its function, in spite of the disruptions caused by the war. The family unit was the basic idea of that great social venture, the Pioneer Health Centre at Peckham, whose work is now largely suspended because so much of the population it served has migrated. But the ideas which animated the Centre go on, and some of them are ably put forward in a memorandum addressed to the Ministry of Health and other Departments over the signature of Dr. Innes Pearse, the medical director.

Dr. Pearse proposes a homestead scheme, which will provide a reasonably healthy and useful life for the wives and children

of mobilized men. She wants to see the evacuated women and children introduced into a society of people like themselves, of which they would become an integral and significant part. If the family is to function the mother and child must not be separated, as they would be if the former went into one of the auxiliary services or into "munitions." Perhaps one-third of the mother's working day must be given to the young child, but the remainder could be devoted to work of national importance, most obviously food production. The running of a mixed farm and garden—a homestead—on an estate of thirty or fifty acres, of which there are many in this country, should be within the capacity of a group of twenty-five to thirty women with two-thirds of a day's work to give on the spot where they are living. Under the guidance of advisers and with the help of a nursery-school worker, the mothers in such a colony would be able to undertake useful self-supporting work on the land, they would take their turn in household duty, they and their children would live in relative safety and under optimum health conditions, and, what is of equal importance, the fathers, to their own great benefit, could rejoin them on the farm during their periods of leave. Dr. Pearse begs the Government to set up a voluntary service of young mothers with children under 5, to begin with, to be called "The Mothers' Auxiliary Yeomen Service." The health overhaul, which was another idea of the Peckham Centre, could be undertaken by a visiting doctor and nurse-laboratory attendant travelling in a motor van to each of a batch of homesteads, and they would also supervise the diet and general hygiene and assure ante-natal and post-natal care and child welfare. It is not pretended that such a scheme could do more than touch the fringe of the vast evacuation problem; but it would at least provide that a certain number of women, made familiar with the land and having had their resourcefulness and initiative developed and their health reinforced, would be ready to stand with their men on the return of the latter from the war, a reconstituted family unit in wholesome surroundings, better able to meet the demands of the new world.

Local News

ENGLAND AND WALES

London's Wartime Hospital Needs

Mr. Charles M. Power, house-governor and secretary, reports that the Ministry of Health has placed at the disposal of the Westminster Hospital 100 beds at an emergency hospital near London. To these beds civilian patients are now being transferred, after initial treatment in the London wards of the hospital. Here, also, out-patient children needing operations for the removal of tonsils and adenoids are being sent. The Westminster Hospital has been able to reopen some forty beds for the accommodation of contributory middle-class patients. The Ministry of Health, at the request of the National Radium Commission, is providing a centre to contain 120 beds for patients needing radium and x-ray treatment. Five of the London hospitals will share the beds. It is hoped that these beds may be the means of avoiding delay which has occurred during recent months, and that the treatment of these distressing cases will not again be interrupted should air raids on London be resumed.

Emergency X-ray Service for Hospitals

A fleet of fifteen x-ray vans now stands ready to answer calls for assistance from hospitals enrolled in the Ministry of Health's Emergency Hospital Service. These mobile vans, fitted with the latest type of equipment, have been presented by the War Organization of the British Red Cross and Order of St. John of Jerusalem. They will be stationed at selected hospitals in London and the Provinces so that calls from any part of the country can be answered. It is not intended to use them for routine work, but they will constitute reserve sets for an emergency caused either by raid damage or by unexpected demands on

a hospital's resources. Each van generates its own current for the x-ray apparatus, which can be operated by cable up to 100 yards away. There is also a dark-room with films and developer. Typical purposes for which these units will be used are: in temporary breakdown of a hospital's x-ray service because of raid damage or the interruption of power supply; to examine cases in the wards of hospitals which have no mobile or portable apparatus; and to supplement the x-ray service at hospitals where, because of the large number of casualties, the normal facilities cannot cope with the demand. The vans will have women drivers, and a radiographer will be attached to each unit. The radiographer, who will be appointed by the hospital at which the mobile unit is stationed, will work in the hospital while not engaged with the unit. The Ministry of Health is anxious that full use should be made of these mobile units. Application should be made to the Hospital Officer or, in the case of the London Sectors, the Group Officer.

Tuberculosis in Lancashire

To meet the need for economy in paper, Dr. Lissant Cox, the central tuberculosis officer to the Lancashire County Council, presents for 1940 a very truncated interim report. He notes that in 1940 the new cases reported of pulmonary tuberculosis numbered 1,394, an increase of 105 over the previous year. On the other hand, the number of new cases of non-pulmonary tuberculosis was 751, or 39 less than in 1939. The death rates from tuberculosis per 1,000 of the population recorded in 1940 were as follows (the average for the five years 1935-9 is added in parentheses): pulmonary tuberculosis, 0.46 (0.44); non-pulmonary tuberculosis, 0.09 (0.09). It is good to read that Lancashire has been fortunate in respect of institutional treatment, because the sanatoria and hospitals, being small, were not commandeered for other purposes, so that treatment and isolation have been carried out without much alteration in spite of the war. Dr. Lissant Cox adds some data on the examination of recruits in connexion with the National Service (Armed Forces) Act, 1939. Since the passing of the Act to the end of October, 1940, the number of suspicious cases referred by medical boards to the county tuberculosis officers was 614. Of this number 78 were already known to the tuberculosis officers. Of the remaining 536, 27, or 5%, were found to be suffering from active tuberculosis (the sputum contained tubercle bacilli in 11); 15, or 2.7%, had quiescent lesions; and 3, or 0.5%, were patients with active disease who had received treatment for tuberculosis under another authority. The total number of recruits examined by the medical boards during this period has not been made known to Dr. Lissant Cox.

SCOTLAND

Post-war Reorganization of Hospitals

Mr. Thomas Johnston, M.P., Secretary of State for Scotland, in a recent address to members of the Scottish Advisory Committee of the Nuffield Provincial Hospitals Trust, urged the need for speed in defining Scotland's post-war hospital reorganization policy. He hoped the Trust would continue to help in propaganda for co-ordinating the voluntary and local authority hospitals and the new State-run emergency hospitals which had been created by the war. Mr. Johnston announced that the whole position was to be examined by a committee of inquiry which his Advisory Council on Post-war Problems had decided to set up as soon as possible. He said it was essential to have a vision now of how they were going to co-ordinate all the hospital services which would provide Scotland for the first time in its history with a surplus of hospital beds. One of the main tasks of the committee of inquiry would be to determine how co-ordination was to be secured and financial aid given to voluntary hospitals "without imperilling their jealously guarded autonomy." Members of the Scottish Advisory Committee of the Nuffield Trust agreed to give evidence before the committee of inquiry if required. It was also agreed to place at the disposal of the Secretary of State information which the Nuffield committee collected when examining the possibilities of regional reorganization of Scottish hospitals.

Correspondence

Radiology and Pelvic Disproportion

SIR.—Prof. Munro Kerr utters a warning against the easy assumption that x-ray examination now provides a lazy short cut to deciding the correct management of obstetric disproportion. I agree with his protest, and should be very sorry if recent publications have given any such impression. The radiologist who lacks obstetric experience, who has had no opportunity of studying the patient, and who cannot calculate with the components of difficult labour, is put in an impossible position when asked to pronounce, in a doubtful case, on obstetric prognosis and treatment; his position is even more difficult than it is when he is faced with a similar problem concerning a patient with a doubtful lesion in the lung. Further, there are many subtle pitfalls in the radiological diagnosis of disproportion, and I, for one, would regard with the greatest alarm any suggestion that the radiologist should reign supreme as dispenser of authority for the performance of Caesarean section.

Nevertheless, are we holding an even balance? Speaking as an obstetrician, I believe that we have been unreasonably tardy in accepting the aid of a valuable tool. It is for us to learn the real uses, and for us to read the meaning—as we can do with increasing accuracy—of the "writing on the wall."

Prof. Munro Kerr refers to a passing criticism I recently made of trial labour. This was taken from a paper dealing with the methods, clinical and radiological, by which pelvic contraction can be detected and its meaning assessed; and was intended to give point to my disapproval of the modern tendency to ignore pelvic measurements and to rely blindly on the method of trial labour for all sorts and types of foetal-pelvic disproportion. This tendency is, in my opinion, as reprehensible as is the extravagant and uncritical enthusiasm for radiological diagnosis which Munro Kerr so rightly deplors. But the careful obstetrician will make intelligent use of both methods. Trial labour achieves its greatest success in dealing with the antero-posterior brim contraction of the rickety flat pelvis. It is indeed amazing to find how extreme is the contraction that can sometimes be safely overcome by the forces of Nature. This I referred to in the paper quoted. But the benefits of trial labour are far less certain when the contraction not only affects the brim but is continued downwards through the birth canal (the simple flat and the generally contracted pelvis), or when there is a true funnel contraction of the pelvis. In such cases a very great responsibility rests on the observer, and too often in hospital practice unfair reliance is put on a relatively inexperienced house officer. Labour progress indeed takes place, but it is painfully, and sometimes dangerously, slow. Nor is the state of the cervix a safe indicator for deciding the duration of the trial, for in these cases the cervix may never reach full dilatation, and the patient, in fact, may never truly enter the second stage of labour. When, then, shall word be given that conservatism has failed and surgery must come to the rescue? When does watchful expectancy become ignorant idleness? Too often, while hesitation prevails the foetal heart stops. Too often the labour becomes so prolonged that Caesarean section is deemed unwise, and a supremely difficult foetal extraction is attempted from below; too often a damaged woman is left to reflect in sadness on the loss of her firstborn, whose sacrifice she can ill understand. This, no doubt, paints the picture at its worst and is the reflection of poor obstetric judgment. But mature experience is not a universal asset, and in the very real difficulties that arise every aid is eagerly seized.

It is precisely for the reason that prognosis varies with the type of pelvis that accurate appreciation of pelvic shape and size, and of foetal size, is of supreme importance in the management of the slighter degrees of disproportion. In doubtful cases the information given by the lateral x-ray picture made during the course of trial labour is specially useful. In my experience this has sometimes helped to decide the issue in favour of Caesarean section before the trial of labour has degenerated into a test of the endurance of foetal life. Much

oftener, however, the examination has revealed a foetal head that has already safely passed through the plane of least dimensions of that particular pelvis, and delivery from below has then been undertaken with some assurance of safety. While it would be idle to pretend that mistakes are never made, increasing experience has given increasing confidence in the value of x-ray findings in such circumstances.

Lastly, Munro Kerr himself states the case for x-ray pelvimetry and cephalometry in breech presentation. Minor degrees of disproportion can then be detected only by radiological means since the head is no longer available as "the pelvimeter of the brim." When external version has failed, and it is clear that disproportion will complicate breech delivery, Caesarean section should be the rule.—I am, etc.,

Radcliffe Infirmary, Oxford, Nov. 22

CHASSAR MOIR.

Vaccinia as a Complication of Vaccination

SIR,—I have been greatly interested in the excellent description by Dr. J. N. Turnbull (November 22, p. 751) of the case of the baby with generalized vaccinia, and having spent years in the study of vaccinia virus in the laboratory I venture to submit two suggestions in the hope that they may possibly be of use should further instances of this rare complication of vaccination occur.

The first suggestion is that, as the viruses of both vaccinia and variola are extremely susceptible to the action of potassium permanganate, which even in a dilution of 1 in 100,000 inactivates vaccinia, a wet compress soaked in permanganate solution should be applied to the vesicles. The virucidal action is inhibited by glycerin, so the latter should not be used as well. The second suggestion is that in a severe case of vaccinia such as that described by Dr. Turnbull trial should be made of convalescent serum if it can possibly be obtained. At the same time as Dr. Turnbull's case, that of a baby girl of 7 weeks, a brother of 3½ years was vaccinated with normal result, and after the tenth day his serum would inactivate the virus; so that as the baby's condition remained good until the fourteenth day the effect of some of her brother's blood or serum might have been tried on her.

The beneficial effect of serum taken fourteen days after vaccination and injected into a case of that other rare complication of vaccination—namely, encephalitis—was dramatic in one of Lord Horder's cases at St. Bartholomew's, and others have confirmed this effect, with the result that the treatment is now generally established. The chief difficulty is to get the serum in an emergency, and a supply of it taken from young healthy adults fourteen days after vaccination and preserved after being dried ought to be available by this time for general use. This should not be beyond the scope of the Blood Transfusion Service. The Germans obtained it—subsequent to the publication of Lord Horder's case (*Lancet*, 1929, 1, 1301)—by taking serum from probationer nurses after the eleventh day from vaccination; but from my observations the fourteenth day is better. This same serum might also benefit severe cases of small-pox.—I am, etc.,

East Molesey, Nov. 24

M. H. GORDON.

National Wheatmeal Flour?

SIR,—I wish to draw the attention of members to an Order in the Statutory Rules and Orders of the Ministry of Food. This was issued in August and remained unknown to us until brought into the light by the *Lancet* last week. It regulates the contents of what is called "national wheatmeal flour." We had, I think, all understood that this flour must contain the germ of the wheat and so supply a fair quantity of the B vitamin as well as the minerals missing from white flour; that it was a protective food. By virtue of this Order 85% extraction white flour coloured sufficiently to make it pale brown and so indistinguishable from a genuine germ-containing wheatmeal flour can be sold as national wheatmeal flour. That is the situation to-day, and as one who has been actively supporting what was understood must be a protective food, and the only cheap one, I wish to make the story a little clearer so that my disgust and alarm may be felt by others. It is not a comforting story.

When the Medical Research Council published their memorandum on national flour (*Journal*, May 31, p. 828) it was generally understood that the new wheatmeal flour was to be made according to their recommendations. This belief was

strengthened when Lord Woolton made his speech to the bakers at their Leicester conference in June. He is reported to have said that on the subject of bread he had been to much trouble, that he had been "advised by the most eminent scientists in the country," and to have mentioned the Medical Research Council in this connexion; and that he had met the millers and a standard had been obtained for the production of national wheatmeal flour. As no other specification had been made public by the Ministry of Food this was regarded as pointing to the adoption of the only specification published—that of the M.R.C. Any remaining doubts were completely dispelled by Circular 2470 received from the Ministry of Health, also in June. This was sent to local authorities calling their attention to the nutritional advantages of making national wheatmeal flour available to patients and staff of hospitals, etc., in their area. It is so clear what Whitehall understood by the term "wheatmeal flour" that I quote two paragraphs.

"The Minister has been in consultation with the Minister of Food on this matter, and he is advised that national wheatmeal flour is now available to bakers. This flour contains the greater part of the germ of the wheat, with some of the finer bran, but excludes the coarser bran. It thus contains not only most of the vitamin B, but also most of the remainder of the vitamin B complex, as well as valuable mineral elements which are removed in producing white flour. National wheatmeal flour is therefore of high nutritional value and is particularly valuable at times when there is restriction upon the availability of other foods from which these vitamins and minerals could be obtained."

"Bread made from national wheatmeal flour should be of a pale brown colour and of a . . . texture closely similar to white bread."

This is a model of clarity; it tells in a plain and straightforward way just what they understood the new flour would contain. It gives definite and positive information about what it would supply, and is not an essay on what wheatmeal should supply. The mere fact that such a consultation had been held is evidence that this Ministry at least was fully aware of the nutritional importance of such a flour. It is also evidence of the source of their information which they felt justified their assurance—it was the Minister of Food himself.

We now know that by this Order 85% extraction white flour coloured with bran, which makes it resemble the wheatmeal described by the Ministry of Health, is what Lord Woolton had decided the country needs in these times. Are we to imagine that this was fully explained at the consultation; that, knowing this, Whitehall issued that circular? In my long experience as a grumbler at our Ministry I have never had anything like this to complain of.

Wheatmeal bread need contain no more vitamin than the white, which on account of these deficiencies it was to replace: no more of the anaemia-preventing iron or the other minerals. A miller may, of course, return all these to his wheatmeal flour, but he will only get the same price for it as he would if he sold the germ separately. What it will provide is to depend on what suits the business of the individual flour mills! So when we order wheatmeal bread we shall not know what we are getting unless we have a laboratory test made of the contents; only the miller will know.

It should be known when the Minister of Food altered his standard; whether it was after or before the meeting of the two Ministers. Was the Minister of Health advised so that he could have that circular withdrawn or altered so as to be in accordance with the facts? It is not clear why the Medical Research Council should have been mentioned at all when their advice was not to be followed; that was misleading. We should be told why their advice was rejected, for in the same speech in which he told them "the most eminent body of scientists in the country" Lord Woolton declared that there was no other body whose advice "could compare" with theirs. After that it is not understood how he can have found a still superior body to advise him and whose advice he chose to follow. We ought to be told who they were, or we may think that their superiority was not unconnected with financial considerations.

The situation is an alarming one when one thinks of how output can determine the result of the war and how much output must depend on nutrition. The disregard for the advice of scientists on this front may be of serious import. One heard at the meeting of the Nutrition Society at Cambridge that when 800 women munition workers were examined by members

of the society more than a third suffered from nutritional anaemia. Can that be without effect on output? Those who hearken to vapourings about "all being well" and "there is no malnutrition in the country" live in a world of their own. What a chance for the iron-containing wheatmeal bread could be found among those munition workers! But Lord Woolton has decided it is not necessary. When will the Ministry of Health direct matters of nutrition?—I am, etc.,

Grimsby, Nov. 24.

S. W. SWINDELLS.

Red Cell Suspensions in Treatment of Anaemia

SIR.—Dr. G. E. O. Williams and Prof. T. B. Davie (November 8, p. 641) emphasize the need in certain cases to produce the maximum rise of haemoglobin using the minimal volume of blood possible. When the haemoglobin has reached 60% they advise changing to fresh blood to obtain the advantages of antibodies and active leucocytes. But they do not mention a fact that I noticed in my much more limited experience—this is, that the amount of blood necessary to raise the haemoglobin varies directly with the age of the blood; this is more marked in the toxic patients.

In their series Dr. Williams and Prof. Davie used concentrated red cells, and the cases quoted in their Table I average 36.5 c.cm. for a 1% rise in the haemoglobin. But the individual figures vary very widely, and one wonders if the average would be much better if the cells were prepared from fresher blood. These all seem to be cases in which there was enough time to warn the blood bank of the transfusion and to send a sample of the recipient's blood to cross-group with suitable donors and to return their fresh blood.

In the cases I have observed, which included those of haemorrhage, anaemias of pregnancy and puerperium, pernicious anaemia, and leukaemia, with the patients' weights varying from 7 to 11 stone, fresh defibrinated blood being used, the amount necessary to obtain a 1% rise in haemoglobin was always between 40 and 43 c.cm.: it was rarely as high as 43 c.cm. So constant was this figure—40 c.cm. for each 1% rise—that one could predict the amount of blood necessary to obtain any required rise in haemoglobin. The haemoglobin estimations were carried out eighteen to twenty-four hours after transfusion, and were always done by the same independent observer, who made the test before transfusion. If fresh citrated blood was employed and the volume of anticoagulant subtracted, then the actual amount of whole blood given was still the same for a 1% rise in the haemoglobin. With citrated blood that was a few days old, still allowing for the anticoagulant, the amount necessary to produce a rise in the haemoglobin rose steadily: seven- to ten-day-old blood being used, it rarely required less than 70 c.cm., and often as much as 90 to 100 c.cm., to obtain this 1% rise.

It seems obvious that the fresh defibrinated blood can compare very favourably with the concentrated red cells as these are prepared now: the results are more regular and the patient has the advantage of fresh antibodies, leucocytes, and red cells, with a difference in volume of only 3.5 c.cm. for each 1% rise in the haemoglobin. If concentrated cells were prepared from fresh blood it would probably require much less than 35.5 c.cm., maybe as little as 20 or 25 c.cm., for each 1% rise in haemoglobin.—I am, etc.,

Newcastle-upon-Tyne, Nov. 21

K. B. ROGERS.

Haemoglobinometry

SIR.—In his letter Dr. Robt. Campbell (November 22, p. 747) mentions his difficulty in deciding the correct method to use the Sahli instrument to estimate the haemoglobin percentage. I should like to suggest that it might be possible to overcome this difficulty by standardizing the Sahli instrument by comparison with a Haldane instrument. The exact technique used during this standardization should be carefully noted and thereafter strictly adhered to. The time which elapsed before diluting might be two minutes or forty minutes, but would be constant in every case.

I think this method would give sufficiently accurate results from "the viewpoint of the general practitioner," and would be simpler and cheaper than carrying sparklets of carbon monoxide.—I am, etc.,

Dunder, Nov. 22.

A. J. E. MILLS.

Loss of Vision after Haemorrhage

SIR.—In view of Colonel H. L. Tidy's article (May 24, p. 774) and Sir James Barrett's letter (November 15, p. 711), a brief reference to the following case, which will be published in more detail later, may be of interest.

A woman aged 35 and thirty-two weeks pregnant was admitted to the Radcliffe Infirmary in *extremis* due to a most severe, concealed, accidental haemorrhage. She had suddenly lost her sight when she collapsed with pain and shock. In a brightly illuminated theatre she could recognize light from darkness, but could not distinguish the outline of anyone standing by her bed. She stated she could recognize a shadow there, but that was all. Ophthalmoscopy revealed no fundal lesion. Before a transfusion was administered oxygen was given with a B.L.B. mask and was continued for five hours. Within twelve hours vision was returning, and three days later the patient could read large type. Since then there has been a complete recovery of sight. Before this patient left hospital she was seen by Miss Ida Mann, who stated that it was probably the administration of oxygen that had saved the retina from destruction. It is possible, therefore, that the wider use of the B.L.B. mask in cases of severe haemorrhage may decrease the incidence of this rare but terrible complication.—I am, etc.,

Oxford, Nov. 19.

JOHN STALLWORTHY.

Nicotinic Acid and Pellagra

SIR.—Your editorial article entitled "The Sprue Syndrome" (November 22, p. 731) contains the statement that pellagra "is curable by nicotinic acid." This statement surely requires some qualification.

It has become increasingly clear in recent years that pellagra is *not* due to the lack of a single dietary factor, as was formerly supposed, but is, in reality, a multiple deficiency syndrome. Besides the classic "three D's" of dementia, diarrhoea, and dermatitis, the "typical case" may present the following additional evidence of dietary insufficiency: (1) nutritional polyneuritis, usually (and probably erroneously) attributed to thiamin (vitamin B₁) deficiency; (2) anaemia, the cause of which is still uncertain in this condition; (3) cheilosis, angular stomatitis, and (4) vascularization of the cornea, which are currently attributed to deficiency of riboflavin; (5) folliculosis, the result either of vitamin A or vitamin C deficiency; and (6) a reduction in plasma protein, no doubt due to the aetiological factor you mention—"an unbalanced dietary deficient in protein." It is evident, therefore, that deficiencies of several dietary constituents ordinarily contribute to produce the clinical picture seen in pellagra. In fact, the only reason why it is possible to recognize pellagra as a clear-cut clinical syndrome is probably because of the uniform composition of deficient diets in those parts of the world where it occurs endemically. In other parts, including this country, where deficient diets are less uniform, certain features of pellagra are quite frequently encountered, but the full syndrome is rare.

The important question is, What part of this syndrome can be cured by nicotinic acid? Any critical clinician with experience of the condition will probably agree that this is a very difficult question to answer. The difficulty is that the average pellagrins improves remarkably on simple bed rest and good hospital care, even if the diet is so arranged that it provides no significant amount of the entire vitamin B complex. An efficient nurse, with the aid of soap and water, can often work wonders with a pellagrins dermatitis. This being the case, it is very hard to draw reliable conclusions from a therapeutic trial of nicotinic acid. However, there is now a considerable weight of evidence that it is at least effective in the relief of the gastro-intestinal manifestations of the syndrome and, perhaps, of the erythematous element of the dermatitis; but as to the psychologic changes—after four years' trial of nicotinic acid the mental hospitals of the Southern States of America are still providing for chronic pellagrins.

So far as I know there is no evidence whatsoever that nicotinic acid is in the least effective in the relief of nutritional polyneuritis, anaemia, cheilosis, angular stomatitis, corneal vascularization, folliculosis, or hypoproteinaemia, all of which are frequently encountered in the pellagra syndrome. Of course, it may be said that these changes are not a true part of the

syndrome, and are merely manifestations of other associated deficiencies. There may even be some who would wish to define pellagra as "the clinical consequence of uncomplicated nicotinic acid deficiency." Armed with this definition, it might then be true to say that nicotinic acid will cure pellagra, but the fact still remains that it will not cure pellagrins. Moreover, it would be impossible to give a clinical description of pellagra as so defined, since a pure deficiency of nicotinic acid, unassociated with any lack of other essential dietary factors, has probably never yet been seen in man. Your editorial implies that the simple administration of nicotinic acid is sufficient and adequate treatment for a case of pellagra, whereas the fact is that nothing short of a radical readjustment of the diet will result in a complete and satisfactory cure.

Your editorial also states that "the incidence of pellagra appears to depend not so much upon the lack of nicotinic acid in the diet as on the failure of the intestinal mucosa to absorb it." It is true that pellagra occasionally arises in consequence of some gastro-intestinal disease affecting digestion and absorption, but, in the common endemic disorder, the obvious inadequacy of the diet is surely a sufficient explanation of the deficiency, without calling in the additional hypothetical factor of faulty absorption.

You also state that "pernicious anaemia is often accompanied by glossitis similar to that of sprue and pellagra, and this is also amenable to nicotinic acid therapy." I am most surprised by this statement, since I had thought that all authorities on pernicious anaemia are now agreed that nicotinic acid has no effect on any feature of the glossitis in this disease.—I am, etc.,

Oxford Nutrition Survey, Nov. 22.

ARNOLD P. MEIKLEJOHN.

Unusual Outbreak of Haemolytic Streptococcal Infection

SIR.—The seasonal epidemic of haemolytic streptococcal infections of the nasopharynx is upon us, and I think that the following brief report of an unusual outbreak will be of interest. Details have been sent to the Medical Research Council by the county bacteriologist, Dr. J. S. Croll, who has been extremely helpful and interested. The late Dr. Griffith, immediately before his tragic death, typed some of the strains.

On January 12 last a woman went alone to the lonely farmhouse where lived her sister and brother-in-law with their large family of children. Three days later she was delivered normally of her thirteenth child. It was discovered eventually that a few months previously she had sent some of her other children away with scarlet fever. On January 16 she developed pyrexia and later sore throat and cervical adenitis. On January 18 the road became completely blocked by snow, and for several weeks no one could approach except on foot or horseback over the fields. The house was thus isolated from all except myself and the foreman's employer. Between January 22 and February 4 three persons in the house developed typical scarlet fever and three tonsillitis without rash. Two of the latter developed nephritis, as did the parturient woman, and all of these patients were extremely ill. The scarlet fever patients were not ill and had no complications. Repeated throat swabs of all, except, curiously, the original case, gave cultures of haemolytic streptococci, Type A, Group 14. I regret now that I did not obtain a culture from the lochia.

The source of the epidemic is not important and I am not concerned with case histories or treatment. My point is this. In view of the accumulating evidence, how much longer must we wait for reform of the existing rules of treatment and notification of scarlet fever?—I am, etc.,

Barton-on-Humber, Nov. 26.

T. H. KIRK.

Sulphonamides and Catgut

SIR.—I have heard the suggestion from more than one source that catgut employed for suturing wounds may have its normal rate of absorption seriously accelerated by the presence of sulphonamide powder, such as one has been using, for instance, in the abdominal wound in cases of gangrenous appendicitis. I have personally not yet found any reason for anxiety through rupture of such wounds, but I thought it would be helpful if others readers could bring forward any first-hand evidence either for or against this impression.—I am, etc.,

Bournemouth, Nov. 27

NOEL F. ADENEY.

Hemiprostectomy

SIR.—The respect due to a surgeon of the eminence of Mr. W. Sampson Handley is enhanced when one has had the privilege of serving as his dresser, and it is therefore with some misgiving that I venture to offer any criticism of his advocacy of hemiprostectomy (November 15, p. 681). Whilst I am in agreement with much of what he says, I feel that the general adoption of this operation even for one case in five would be a retrograde step. The figures he quotes from Thomson-Walker to support this proportion as suitable cases refer only to the intravesical projection and not to the all-important intra-urethral enlargement; and the conclusions of the same author that "the apparently normal lobe shows changes on section and microscopical examination which correspond exactly to those of the large lobe" are confirmed by the routine examination of all prostates in which both lobes are removed.

I would agree that the maintenance of continuity of the vesical and urethral mucous membranes posteriorly is an advantage, and the restoration of this continuity is one of the important principles of the Harris operation; the intra-urethral method of digital enucleation recommended by Harris (*Brit. J. Surg.*, 1934, 21, 437, 442) is designed to leave intact the verumontanum and the urethral mucosa below it.

The shock produced is due to a summation of all the traumatic stimuli set up in the whole operation, and it is difficult to believe that the shock from hemiprostectomy is only one-half that of total prostatectomy. In any case the shock can be minimized by a suitable combination of anaesthetics and by gentle rather than rapid enucleation.

Mr. Sampson Handley states that he has no experience of later enlargement of the residual lobe after hemiprostectomy; I have recently seen and operated upon such a case. Left hemiprostectomy was performed by one of Mr. Handley's colleagues in June, 1933, for a man of 57 with acute retention (two-stage operation). In May, 1941, he returned with acute retention: there was gross urinary sepsis and his general condition was poor. The remaining right lobe was moderately enlarged on rectal examination, but was seen on urethroscopy to project to the left and to produce much distortion of the urethra; on removal it showed the usual changes of senile enlargement. This patient died six months later from hypertensive failure and auricular fibrillation.

To compare hemiprostectomy with endoscopic resection seems to confuse the issue; endoscopic resection undoubtedly has an important place in prostatic surgery, and it may be mentioned as a personal experience that where an adequate amount of tissue is removed in the first place by resection from a benign enlargement there is little tendency to a return of obstructive symptoms later.

After this preliminary report I shall await with interest the after-histories of the two patients operated upon this year and of the others for whom the operation has been done, but on the present evidence I am unconvinced that it has anything to offer over the accepted methods of treatment.—I am, etc.,

London, W.1, Nov. 24.

E. W. RICHES.

SIR.—I have read with interest Mr. W. Sampson Handley's article on hemiprostectomy (November 15, p. 681). In it he states that transurethral resection accomplishes "at best a partial removal of the adenomatous mass, the rest of which may continue to grow with a return of obstructive symptoms." Surely this description is more readily applicable to the operation he describes than to the modern "punch" operation, perfected by Gershom Thompson and Emmet. I have had the privilege of seeing Mr. Wardill of Newcastle using the "cold" punch, and can assure Mr. Sampson Handley that the removal of adenomatous gland is very nearly complete: "... as much of the enlarged gland is removed as possible." This in many cases must amount to about four-fifths; in some cases as much as 64 grammes has been removed at one sitting" (Wardill, W. E. M., *Lancet*, 1941, 2, 127).

The statement that "it seems likely that hemiprostectomy will have a lower mortality and will offer more security against the recurrence of obstruction" (than punch prostatectomy) does not seem to be a fair conclusion to draw from the two cases quoted, and is indeed rather surprising, when the fact that in 1935 Gershom Thompson published a series of 451 punch operations without mortality was noted earlier on the same page.

Furthermore, the convalescence after the punch procedure is very considerably shorter than with open operation—usually about eight to fourteen days. Also the patient is out of bed and walking about one or two days after operation, a most important point when dealing with elderly men. Lastly, in the hands of experts the punch method is applicable to all cases, whereas hemiprostectomy can at best only be applied on comparatively rare occasions.—I am, etc.,

Lancet, Nov. 25.

G. A. BAGOT WALTERS.

X Rays in Treatment of Inflammations

SIR.—It is difficult to write with moderation in disapproval of the comments at the end of the annotation on "X Rays in the Treatment of Inflammations" (November 15, p. 700). The suggestion contained therein that hospital or armament works casualty officers after a few weeks' training would be competent to prescribe and administer x-ray treatment is courting disaster. The inadequately trained and insufficiently experienced in x-ray therapy would be a grave menace to patients, to themselves, and to any organization that they serve. It would be infinitely preferable to forgo the doubtful advantages of ill prescribed and administered radiation than to risk the calamities that can follow misjudgment.

Drs. Pendergrass and Hodes in their article describe their technique under five headings, and complete their prescriptions under each of the conditions with which they deal. Their technique includes the use of what has become familiar to radiologists as (1) near-distance therapy, (2) medium therapy, with and without filters, and (3) deep x-ray therapy: the whole armamentarium of modern x-ray treatment, three separate and distinct x-ray installations. The technique is not simple and the doses required are not, as the annotation states, so small that there is no risk of radiation injuries. On the contrary, the authors, dealing with bursitis and with the shoulder under consideration, state: "Occasionally six or eight exposures have been necessary. Under such circumstances multiple portals have been utilized to preserve the skin tolerance to irradiation." They have thought it desirable to draw attention to this in the text and in the caption. Again, under erysipelas, although they have had no untoward results, they say: "Patients should be warned of the possibility of epilation and a signed permission obtained before starting roentgen therapy." Special warning is also made in connexion with the use of near-distance therapy and the treatment of verrucae and similar lesions. The authors are not unmindful of the risks.

The interpolation in the annotation of the bald statement of "100 to 200 r daily for three to five days," totally unqualified as to filtration, area and how measured, with or without back-scatter, is no "so small" a dose, and it may prove to be misleading. All who have read the annotation in question should read Drs. Pendergrass and Hodes in the original, when they will recognize how dangerous the concluding advice of the annotation may be.—I am, etc.,

London, W.1, Nov. 25

H. COURTNEY GAGE.

Sciatic Pain

SIR.—Your leading article (November 15, p. 698) gives a true picture of the present position. "The major problem remains" indeed. But does "the next step lie in the direction of pathology"? And are not the terms used misleading, rather than only "quite devoid of meaning in terms of morbid anatomy"?

Idiopathic sciatica, lumbago, and related processes come and go in the vast majority of cases. Such pathological changes as may occur in the tissues must correspondingly be assumed to be reversible. Biopsy of the suspected organs is hardly ever possible since surgery is not called for. Where it was done, as in the work by F. and M. Lange (*Die Muskelhäuten oder Myogelosen*, Munich, 1931), there was no histological evidence of any change, certainly none of inflammation, as indicated in terms like *myositis* or *fibrositis*. Nor was inflammation found in the few cases of chronic sciatica examined post mortem. Spielmeyer found signs of thickening of the nerve sheath and degeneration of the nerve fibres. It is safe to state that whatever the underlying pathological process may be it is not—in the vast majority of cases—a true inflammatory one, and the terms we use are wrong. Animal experiment is not likely to

help us, since pain is the only subjective symptom. And objective evidence of its existence will only be obtained if the animal limps. It is doubtful whether, owing to their coat, animals are likely to suffer at all from the passing forms of "muscular rheumatism" or neuralgia.

With the three usual paths of inquiry—biopsy, post-mortem examination, and animal experiment—blocked, how can we hope to arrive at a clearer picture of what causes the painful state, and what happens morphologically while it lasts? May I suggest that an indirect approach by way of a working hypothesis might prove useful to those who see large numbers of such patients and who have facilities for physiological research. Three sets of facts form the basis of such a working hypothesis: the exact history of the patient and the closely followed course of the condition as indicated by the curve of his main symptom, pain; the pathological physiology of the vegetative nervous system, so far as it is known through the work of Krogh and Lewis; and the normal anatomy of the vascularization of muscles, tendons, and nerves.

The common history of the attack of both lumbago and sciatic pain is that the skin of the patient at the onset was wet, either because of damp weather or through sweating, or both. Common, too, is a state of physical strain or exhaustion—frequently a state of overwork or worry and an excitable mental make-up. True trauma, unless "asked into" the patient, is rare. Common is a start of pain after bending down, involving mechanical pressure by belts, etc., on the lumbar region. The pain in lumbago starts more or less at its worst and wears off within days or a week or two; the pain in sciatica takes a few days to rise to its peak, remains at a high level for weeks, and wears off very gradually. It starts proximally, extends downwards, and ends eventually by first leaving hip and thigh and later the leg and foot.

That wet skin is a better conductor of heat and cold than dry skin is known. That cooling of deeper tissues under wet skin is possible is recognized. That a state of unbalance of the tension of arterial and capillary walls is set up by changes of temperature, leading to spasms of contraction or dilatation with consequent interruption or slowing down of the flow of blood, we have been taught by Lewis. In order to understand the predilection of painful reactions related to muscle groups, tendons, and nerves, we have to remember that in muscles several factors combine to oppose a smooth passage of blood—the normal or increased muscle tonus, stretching over joints, compression under belts. Tendons, fascia, ligaments, and nerve sheaths have in common a poor supply of blood vessels and no or hardly any provision for the setting up of a collateral circulation. It must be remembered that, for example, only one nutrient artery enters the sheath of the sciatic nerve below the junction of its roots, and this does so at an angle which favours mechanical closure of the lumen quite apart from spasm. (Little is known about the vasa nervorum. On 200 transverse serial sections I convinced myself that there is really no other source of arterial blood along the whole course of the nerve.) Any temporary stoppage of the supply of fresh blood in these tissues therefore must be followed by more drastic consequences than in tissues with more ample vascularization or greater chances for collateral circulation. Short of total ischaemia and consequent atrophy or necrosis, we must assume that intermediate and reversible states of degeneration may be caused which most likely are in the nature of what is known in the heart muscle as "cloudy swelling." Such swelling in turn would lead to compression of veins and lymph channels, increasing the swelling and setting up a vicious circle even if the causative spasm of the artery has already worn off. Not before normal circulation is re-established will this swelling be absorbed. As long as it lasts it is bound to cause pain by distension and pressure on sensory nerve endings, especially in a tissue as dense and tight as a nerve sheath. With or without treatment normal circulation is being re-established—slowly in a long nerve, quicker in a muscle or tendon. And once normal conditions have returned nothing would show that the process had taken place.

The hypothesis of a disturbance of circulation as the basis of myalgias and neuralgias is not new in itself. But I do not remember having seen a clear description of its possible pathological course. It is as difficult to prove to be right as to disprove. And while many clinical facts are in its favour it may

not ultimately prove to be right. As it is, it helps us to understand many otherwise isolated features. The neuralgias of a few hours' duration can be understood as well as the effect of cooling on a motor nerve in Bell's palsy. Neuralgias in conditions known to involve the vessels—as diabetes, diphtheria, lead poisoning—may be viewed from this angle. And some of the difficulties in therapy may be explained. Heat, for example, seems to help while it lasts, but warmth in bed is not liked (increased congestion?). The success of vitamin B treatment may be based on the action of nicotinic acid. Not more can be said than that here is a working hypothesis which might help understanding and further inquiry.—I am, etc.,

London, W.1, Nov. 24.

L. MICHAELIS.

Industrial Medical Boards for Women

SIR,—The letter from Dr. E. M. Herbert on industrial medical boards for women raises an important issue, but why should such not be established for industry in general? This is a way in which medicine can make an important contribution to the war effort. To suggest two directions only: first, there should be a system of grading and classifying labour at the labour-engaging centres. So urgent is the demand for labour in the heavy industries that all sorts of derelicts have been mobilized in the former distressed areas and sent, at no small expense, to attempt work for which they quickly prove to be totally incapable. We have had epileptics, chronic asthmatics, cardiac cases, and the like sent to factories where only men physically fit for long hours of heavy manual work are of service. The most casual examination of many of these would have eliminated this waste by frankly writing off the applicant as unemployable, or by diverting him to a job where he might be of use. Secondly, as regards the movement of labour under the Essential Work Order, where a factory has its own medical officer he is often able to rebut statements, frequently grossly exaggerated, by an employee to the effect that work and conditions are "ruining his health." But there are hundreds of factories on important war work, too small to have a doctor on hand, which are at the mercy of any employee able to bring a certificate labelled "Bronchial catarrh: recommended for change of employment," and who regards such as a charter sanctioning immediate release. True, the National Service Officer, if he is so moved, may refer the case to a referee, but such an officer is chosen quite casually from some Government Department and has not necessarily any knowledge of industrial conditions. The comments of industrialists on this lax system and on the ease with which such certificates are obtained are unprintable, though I acknowledge that in this area certificates are now worded much more cautiously.

Medical boards are judged to be essential in a system of military conscription. They have an equally important service to render to the country in a system of industrial mobilization. Their establishment might make the existing tentative element of compulsion in industry less uncourageous and full of loopholes than it is at present.—I am, etc.,

Nov. 24

A. H. DRIVER.

SIR,—Dr. E. M. Herbert's letter (November 15, p. 711) interests me very much and at the same time causes some perturbation. His letter implies that there exists in industry today a state of affairs which is truly appalling, and as chief medical officer of a group of factories employing some 31,000 workers I feel that I cannot let his allegations pass unchallenged. I would suggest that Dr. Herbert's experience of industry proper must indeed be limited, otherwise he would have hesitated before making the sweeping statements he does. The entirely erroneous impression he creates about lack of selection, lack of supervision, must, I feel, be corrected at once. Dr. Herbert has completely ignored the fact that by law all factories engaged on munition work and employing women must provide adequate welfare supervision, and, depending on the numbers employed, appoint nurses and part- or even whole-time medical officers. Dr. Herbert further states that there is no medical examination of females. This is quite untrue. I would suggest that he should have got in touch with the medical and welfare staff of any large concern in this or any other district before making a blunder of this magnitude. I can say definitely that, had

he done so, he would have found that the examination and supervision he maintains are being neglected are being most conscientiously carried out. The *British Medical Journal* is widely read in the U.S.A., and I feel that it is my duty to offset the entirely misleading impression Dr. Herbert's letter must create in that most friendly country.

The question of medical boards throughout the country is quite another matter; but why only for women? I should like to see such boards set up by the Ministry of Labour, not to supervise but to advise employers. Considerable difficulty is being met with to-day by reason of workers of both sexes claiming that their health is being injured by this job or that job, night shift or overtime. Frequently the works medical officer is asked to give his advice in such cases, and often finds himself in disagreement with the private doctor's opinion. This practice, I submit, is most undesirable, and such questions should be dealt with by a medical board of experts.—I am, etc.,

Nov. 24.

NEIL G. MARR, M.B., Ch.B.

SIR,—It would be interesting to know on what data Dr. E. M. Herbert (*British Medical Journal*, November 15, p. 711) bases his sweeping assertion that "women entering munitions receive no medical supervision in the factories." The Ministry of Supply has established in all Royal Ordnance Factories medical departments which are being developed and expanded as the factories grow in strength, and in these establishments, where the weekly labour intake is very large, every new employee, from manager down to the humblest process worker, has to pass a medical examination before being taken on. Applicants are examined with a view to the particular work to be done and are graded accordingly, different standards of physical fitness obtaining in the different factories. For instance, a girl who is fit to make shell and bomb cases may be quite unfit to handle the high explosive with which they are filled, and vice versa. These examinations are carried out either by the factory medical officer or else by outside practitioners, the former, in my opinion, being more satisfactory, as the works doctor is in a much better position to assess the hazards of the various processes.

Once in the factory the worker comes under the supervision of the medical officer—in the larger establishments there are several full-time medical officers—and has the right of appeal in all cases where she feels she cannot for health reasons carry out the job to which she has been assigned. The medical staff also supervise and treat so far as possible all cases of industrial disease and accident, and also periodically inspect those workers who are exposed to special health risks.

I cannot speak for the other Ministries, nor of private enterprise working on Government contract, but I believe I am right in saying that works medical officers are being employed in ever-increasing numbers, and that before long the factory doctor will be an integral part of the factory management.—I am, etc.,

Nov. 24.

CATHERINE N. SWANSTON,
Factory Medical Officer.

Economy of Medical Man-power

SIR,—In view of the urgent need for medical officers in the various Services, it is of the utmost importance that (1) overlapping by the various Services should be eliminated, and (2) that medical officers in any Service should be used as economically as possible.

In regard to (1) there is no need to multiply instances, but I will quote one only—250 aircraftmen were sent to one of the healthiest spots in England: presumably they were all fit men, yet, although there was a naval hospital in the place with naval surgeons, and at least two military units with regimental officers, a medical officer R.A.F.V.R. had to be posted there. There is, I believe, a Commission looking into this matter now, but a medical officer recently told me that he understood the Commission was in his neighbourhood, but that although he had some excellent constructive suggestions to make he did not know how medical officers were selected (his phrase) to give evidence.

In regard to (2) there is at present in the Army a great number of doctors employed on non-medical jobs. I don't think that matters are as bad as in the last war, when I held the

post as officer in charge of Divisional Laundry on the outskirts of Bethune.

(a) *Clerical Work*.—A great deal of this could be done by physically low-grade non-medical officers, or, even better, by A.T.S. officers. It may sound revolutionary, but I can see no reasons why the D.A.D.M.S. of a Division should not be an A.T.S. officer. Voluntary hospitals of the size of Bart's and the London are, and have been for long years, administered perfectly satisfactorily by lay staffs. And many men in big positions find a lady secretary very satisfactory. I feel that our own profession owes much to the loyalty, devotion, and efficiency of the private secretaries. Where indeed would Harley Street be without the secretaries? If it is thought to be too much to appoint a lady to act as secretary to the A.D.M.S. of a Divisional H.Q. likely to go over-seas, instead of having a D.A.D.M.S., the same argument could not apply to A.A. Divisions or Area Headquarters and junior home staff appointments.

(b) *Sanitation*.—The inspection of markets, lodging houses, and alleged sanitary defects in our great cities is carried out by non-medical sanitary inspectors. The R.A.F. place a bomber in charge of a sergeant though officers may form part of the crew. Why, then, could not "hygiene sergeants" R.A.M.C. be appointed to inspect camps, etc.? I suggest that such a sergeant on finding any defect should make a report in duplicate, either using an indelible pencil and carbon copy or typescript if he can type and machines are available, one copy to be sent to the O.C. unit concerned and one copy to the M.O. i/c sanitation of the area (corresponding to civil M.O.H.). A fortnight later he should visit the camp again. If all is well now, a second report should be made as before. The reports in the M.O.'s office would cancel out and no action would be required, but if the sergeant found that no action had been taken at the camp he should issue a second report, preferably on a different-coloured paper—say, pink (for rapid recognition). The M.O. i/c sanitation would visit the O.C. of any area on which he had received a "pink report" to find out (i) why the sanitation was defective, (ii) why it had not been remedied after the first report, and (iii) if he considered it necessary to report the matter to higher authority to inform the O.C. of his intention. Most O.C.s are as keen as anyone to have good sanitation, and, as a rule, on his attention being drawn to any overlooked fault, he will take immediate steps to remedy it. By these methods M.O.s would be freed to do purely medical work.

This letter is already overlong, and so I will not elaborate that side of it, but increased facilities for carrying out minor medical and surgical procedures and a better clinical supervision would shorten the time spent by the soldier in receiving treatment. A colonel in the last war asked me: "How is it that in civil life an employee can have a tooth out and be back at work in under an hour, but if I send a soldier to get a tooth out I don't see him again for six weeks?"—I am, etc.,

Hove, Nov. 27.

H. J. MCCURRICH.

The Nation's Dental Services

SIR,—Your article on the nation's dental services (October 4, p. 488) interested me greatly. The memorandum, to my mind, is perhaps one of the most important and far-reaching of any on the subject of dentistry. The great danger is, however, that views expressed will be allowed to lapse into obscurity in the maelstrom of war and that nothing further will be done.

It is a healthy sign that the students themselves have realized that the foundation on which our study of dental disease is based is unsound and unscientific, which is certainly the case. The link between so-called dental disease and systemic conditions is very real and intimate, and if only it were realized that in the teeth we have the most sensitive "indicators" of upsets in metabolism the whole science of dentistry would be revolutionized. There would be no more talk of the status of the dental surgeon; he would become a key man in our study of disease in general.

All this, however, can only come about if the whole foundation of dental training is altered and more time is spent on the biochemical side of dental disease. We should ask ourselves more often why dental caries or pyorrhea is present rather than treat the condition by fillings or extractions. To-day, in dentistry, we are only treating the symptoms of metabolic upsets

and not treating the causative factor of the symptoms. We have for too long taken the *ipse dixit* of our pastors and masters for granted, and followed blindly in their misleading and bewildering footsteps, with the net result that dentistry to-day is not a science but a highly specialized symptomatic treatment.

If only the memorandum is followed up and acted upon by the younger members of the profession it may well be that it will lay the foundation of a more scientific outlook on the training of dental surgeons. More important still, it will bring together the medical and dental professions in a closer bond than ever before, to the great benefit of patients.—I am, etc.,

G. E. KING-TURNER,
Capt. R.A.M.C.

London, Nov. 21

A Human Ostrich

SIR,—The following case is so out of the ordinary that I think its publication may be justified on that ground alone.

A man aged 25 years was in prison, where he stated he had swallowed various articles. He was removed to a London hospital for x-ray examination, but at the hospital he managed to effect an escape, and was recaptured; in view of this behaviour it was thought necessary for him to be operated upon within prison walls. He was transferred to hospital on May 17, 1940. An x-ray examination made the same day showed (1) two long metal bodies and a big belt-buckle in the area of the stomach, (2) a screw in the right iliac fossa, (3) a long needle near the ileo-caecal junction.

That evening I operated upon him under general anaesthesia, opening the abdomen by a right paramedian incision. From the stomach I removed (1) a metal punch, (2) a spoon handle, (3) a tin prison-knife, (4) a buckle, (5) a piece of a metal comb, (6) a picture hook, (7) a piece of glass (this I had to work back from the duodenum through the pylorus). I found a needle lying partially through coils of small intestines and in the peritoneal cavity directly over the right iliac vessels. It appeared to have worked through the intestinal walls very easily. Later on he passed normally the screw which had been seen in the right iliac fossa. The third day after the operation, when he was left for a few minutes, he was found standing on his bed looking out of the window at the view. He made an uneventful physical recovery, but his mentality degenerated, and on June 8 he had to be certified insane, and was transferred to a civil mental hospital, from which he escaped.

On September 15, 1941, he was again in custody and admitted to prison with the history of having pushed a needle into his chest. There was a small scratch at the site of entrance internal to the left nipple. X-ray examination showed the needle lying to the left of the sternum in a slightly vertical line point downwards, and the lateral view showed it to be inside the thoracic cavity. I opened the chest with a horizontal incision over the sixth rib, and resected one and a half inches of this rib to open the pericardial cavity. Unfortunately the needle could not be found free in the cavity. The heart was beating strongly, and it appeared that the needle lay in the muscle wall: I did not feel justified in attempting its removal, especially as the anaesthetist was by then worried somewhat by the man's condition.

On September 24 he passed four large pieces of glass per rectum, which did not injure him in any way. These he admitted swallowing about ten days previously in prison. He developed an empyema on October 13; I resected a part of rib and drained this: fortunately he made an uneventful recovery, the wounds being practically healed on October 30.

The special points to be noticed are (1) that he could swallow large foreign bodies and (2) that he could pass glass fragments without any damage to himself.—I am, etc.,

J. W. MCK. NICHOLL, M.D., B.Ch.

Sarcoma treated with Coley's Fluid

SIR,—While I was acting as locum for Dr. G. W. Ayres, the Priory, Chippenham, a male patient aged 33 consulted me. Both Mr. C. Kindersley and Mr. Fuller, jun., of Bath saw him with me: the growth observed was x-rayed, and a biopsy was done. The growth was huge and covered the left scapula, and was diagnosed as a sarcoma. Mr. Fuller removed

Psychiatric Problems in Wartime: A Plea for Caution

SIR.—The interesting article by Captain R. F. Tredgold (July 26, p. 109), including as it does detailed observations upon psychotic states occurring in soldiers and their prognosis, together with a description of methods of treatment, gives cause for careful thought, and seems to prompt the question as to whether the present is the time to arrive at conclusions concerning problems of the deepest psychiatric significance.

While it may be of the utmost importance for psychiatrists carefully to record their observations and impressions of the clinical material with which they are called upon to deal in time of war, it is submitted that it will be some time before the opportunity for proper assimilation and mutual discussion of this experience and its implications for psychiatric theory can be obtained. For example, the present war came upon us before it was possible to arrive at scientifically based conclusions as to the precise value and sphere of beneficial application of the various forms of shock therapy. Service needs and the associated demand for simplicity and speed in application required the adoption of Raven-Penrose progressive matrices testing upon large numbers of men before there had been opportunity for full evaluation of this method. The investigation of amnesias, etc., under artificially induced states of narcosis—for example, injection of sodium amytal—prompts certain fundamental questions as to its bona fides from the psychopathological standpoint. Various methods of treatment require to be employed on empirical grounds for their symptomatic value alone and in the absence of suitable checks or controls. This may be admissible, but there appears to be a danger of hasty conclusions being formed from consideration merely of results. Further, when compared with the whole field of psychiatric case material, Service cases, though numerous and a formidable problem at the present time, are nevertheless a limited and selected group developing under artificial environmental conditions.

A case in point is the discussion concerning the nature of depression. It may be that the views expressed by Curran and Mallinson (March 1, p. 305) find a substantial measure of agreement among many psychiatrists, while others will continue to subscribe to the views of Ross and others touched upon in your leading article of July 5 (p. 21). But while it is admitted that in many instances the task of differentiating between "endogenous" and "reactive" depression constitutes a severe test of the psychiatrist's clinical acumen, surely there is danger in teaching the student that "distinction between neurosis and psychosis is at times convenient but without substance," when upon that distinction being made at as early a stage as possible in the development of the mental illness the mental well-being, future, and even the life of the patient may depend.—I am, etc.,

Liverpool, Aug. 7.

S. BARTON HALL.

Depressive States in the Soldier

SIR.—My attention has been drawn to Captain R. F. Tredgold's statement in his paper on the above subject (July 26, p. 109) that I "diagnosed the psychotic type [of depression] by the possession of insight." I hope and believe that it is by a mere *lapis calami* that Captain Tredgold has credited me with this feat, however one interprets his pleasingly ambiguous phrase. To avoid any possible misunderstanding, however, please let me state that if he refers, as I assume, to the patient's insight I have never held or expressed the opinion which he seems to attribute to me. If the word "absence" were substituted for "possession" the sentence would at least be in harmony with my views so far as it goes.

I readily admit the difficulty of assessing insight, but I think most people recognize nowadays that psychiatry is a difficult specialty. I would also suggest, with respect, that in it, as in all other specialties, experience sometimes helps a little.—I am, etc.,

London, W.1, Aug. 3. HENRY YELLOWLEES, M.D., F.R.C.P.

Air-raid Noises in Psychotherapy

SIR.—I was very interested in the article by Majors F. L. McLaughlin and W. M. Millar (August 2, p. 158), and I feel the authors are to be congratulated on the ingenuity which they have shown in getting gramophone records of the actual noises. I foresee great use being made of this type of therapy, especially

where the psychotherapist can control the volume of the noise at will while the patient is on the couch, and thus be able to work up "the dose." I hope it will be made possible for those doing this type of work to obtain similar records.

Just after the last war I was in a Ministry of Pensions hospital dealing with war neuroses, and I found the same difficulties—that is, that the men were noise-sensitive. The method which I used was in some way similar to those described in this article. I used to get the men to talk about their war experiences until they were very conversant with the anxiety-provoking incidents, and then I would get them to take a blanket out into a field at the back of the hospital (which was near a railway line), lie down, and relax, and when they saw a train approaching I suggested that they should close their eyes and take their minds back to their experiences in France and link up the emotions which they felt with the noise of the passing train. In a large number of cases the men had violent abreaction coupled with an increase of memory for the actual happenings. After a few weeks of this treatment the majority were able to go into the town near by without suffering any ill effects from the noise of traffic, which had hitherto caused them acute anxiety.

In considering this type of therapy now, in view of my past experience, I cannot help but feel that much greater use should be made of transference relations between patient and therapist—first by adopting the attitude, "We together are facing these difficult situations which proved too much for you when you were alone"; and then, when the patient's self-confidence has been restored, a process of handing back to him the sense of his own responsibility as an adult and a competent member of society.—I am, etc.,

Aug. 5.

D. N. HARDCASTLE

SIR.—If it was Herodotus who declared that history repeats itself, he will find, if he reads the *B.M.J.* in Olympus, remarkable evidence in the article by Majors F. L. McLaughlin and W. M. Millar on the use of air-raid noises on the gramophone as a form of psychotherapy (August 2, p. 158). It certainly recalls with irresistible and entertaining vividness the medicine-man treating disease with his tom-tom and other cacophonies.

Although it is regrettably true that much of the practice of psychiatry at the present moment is empirical in character, one feels compelled to ask: Is there not a limit beyond which the descent into the extra-rational should not be pursued? If the answer is in the negative and the implication follows that symptomatic treatment is good enough, however achieved, I would like to suggest an improvement. It is that, on the conclusion of the gramophone treatment, a bellicose attitude should be stimulated in the patients by teaching them a war dance. In this the Gaumont British News, I am sure, could help from a selection of their films of Darkest Africa. Finally, the treatment could be properly rounded off by "conditioning" the patients to a record of Herr Hitler delivering one of his celebrated harangues. But that perhaps would be going too far!—I am, etc.,

London, W.1, Aug. 4

FREDERICK DILLON.

Cardiac Arrest during Anaesthesia

SIR.—In reply to Drs. H. J. Brennan, J. W. Patterson, and Mr. F. R. Brown (August 2, p. 175), I can state that pure chloroform anaesthesia has not been used in any of the hospitals in the many parts of the country where I have worked. The forty cases represent the collected experience of over twenty years. Half of this time was spent in senior resident posts, where the proportion of serious emergency cases was very high. During this period my anaesthetists were for the most part hospital residents, and although I have not made statistics I do not think that the cases of cardiac arrest were unduly high on this account. In the case quoted in my paper the anaesthetic was administered by a professional anaesthetist of the highest attainments, whose skill I appreciate.

I suggest to Dr. Patterson that a surgeon with a penchant for the nerve-racking ordeal which the necessity for cardiac massage entails must be about as common as a general practitioner with a partiality for puerperal sepsis.

I should like to call attention to an error in my article; "Darling and Lane" should read "Starling and Lane" (July 19, p. 85). I am greatly indebted to Dr. Edwin Starling, who, in

their tasks. They had no choice in the matter. While it is true that much of the modern hospital's work is to restore men and women for their industrial and domestic occupations, it is only a fraction of their missions. Again, we have to remember that the slave of the Roman Empire had little in common with his namesake of *Uncle Tom's Cabin*. In many cases the Roman slave-owner was on terms of intimacy and friendship with his slaves; as boys they were probably brought up and educated together. From the slave class, too, were recruited many members of the "learned" professions—notably the teachers and physicians, both of whom Juvenal associates with tight-rope artists, fortune-tellers, and attendants at the public baths! We have, then, to keep in mind this personal relationship of master and slave when we are tempted to deny a spirit of altruism to the founders of Claudian infirmaries.

Dr. Cook castigates the system whereby the shepherd "wrapped in the fleeces of his flock" goes to the private home while his shorn sheep are relegated to the municipal hospital. An analysis of that will probably give us good clues towards proposals for a revision of the hospital system. Why does he go to be "fleeced" at a private nursing home? Because (a) the medical profession expects a man of his position to do so; (b) the municipal authorities no less look to him to do this; (c) the voluntary hospital authorities will darkly hint—or pointedly suggest—that their beds are not for him; (d) the hospital for which a "works" card is necessary will not receive him without the very form for which he has no qualification, as he is not a contributor to the "scheme." In other words, our ideal system will have to take account of all four of these factors.

Now the obvious defect of the voluntary hospital is that it makes essential work depend upon uncertain charity. The manifest defect of the municipal hospital is that it allows the typical "high-handedness" of officialdom to invade what is basically a personal service. The glaring inefficiency of a hospital supported by workers' contributions is that it leaves out of account the man who cannot subscribe and "the stranger that is within our gates." But both the voluntary and the works subscription hospital lead to a sense of ownership in the community which is at once valuable, and absent in the instance of the municipal hospital. Why this is lacking in that case I cannot tell: I mention it as the conclusion to some years of experience.

There seems little doubt from my own observations (I was a member of the staff of one of our large voluntary infirmaries) that the future of the hospital lies either with the municipal or subscription (covenanted) supported type. Now Dr. Cook has surprised me by suggesting that the tending of the sick should be placed on a level with sewage disposal. Surely he will allow that a man's illness is in a much deeper sense a personal thing than his ashes, old newspapers, and empty sardine tins. Sickness belongs to a man as refuse does not. That fact must be taken into account in any plans for the future of hospital treatment.

I have been surprised that the control of hospitals entirely by the medical profession does not feature prominently as a suggestion in the discussions on this problem. Briefly, I believe that the facilities for hospital treatment and care ought to be the property of the accredited medical practitioners of the particular community. The points to be kept in mind are:

(1) The medical profession will be absolute in its rightful sphere. This will avoid the ridiculousness of the average committee of a typical voluntary and covenanted-subscription hospital and the "prison governor" methods of the majority of the superintendents in municipal hospitals. Let the medical profession learn the lesson from the teaching world. Let us have no counterpart of the "touting" for appointments of "the butcher, the baker, and the candlestick maker." (2) There will be a sense of ownership by the community. I have already mentioned this as one of the desirable features of the non-municipal hospital. The community will feel its responsibility towards its clinic and hospital. (3) There will be no closing of doors against personal service and benefactions to the hospital; there will be scope for these under the jurisdiction of "the profession."

We have to rid people of the idea that, even if we allow that the care of the sick is a very personal service, the adequate

provision of hospital and medical facilities can rest on a haphazard voluntary basis. The teaching profession is, nowadays, well esteemed; we do not despise the schoolmaster because he draws an adequate salary from a well-provisioned municipal undertaking. But time was when the training of the young was regarded as a personal service, and, therefore, to take money for doing so was mean and despicable. Time was when the professional schoolmaster was ranked in society with the man who hawked kippers in the street. Whatever "scheme" is finally selected will have to make its way against prejudice and misunderstanding. But the more it preserves of the best features of the old voluntary hospital system, so much the more will it commend itself to "us, the people." I venture to suggest that my scheme for absolute ownership by "the profession" embraces those aspects. I should be glad to have the observations of "the new owners"!—I am, etc.,

St. James's Vicarage,
Darlington, Nov. 14.

KENNETH HARPER.

SIR,—The voluntary hospitals claim to treat the sick better than do the municipal hospitals by reason of possessing superior tradition, atmosphere, standards, and exponents. The following would appear to be among the chief virtues of the voluntary hospital system:

1. It is a personal and flexible form of local self-government, reminiscent of democracy, specially adapted to each separate hospital and therefore well calculated to influence the conduct of those in direct contact with the sick, as well as producing a readier consent of the governed.
2. It works to broad principles rather than written rules.
3. It shows a full appreciation of the value of local *esprit de corps* and supports it as a policy.
4. It acknowledges that continuity of standard is essential and pursues this as a policy.
5. It has no place for the party politician, his whims, his wiles, and his nostrums, and provides no privileged opportunity for his public advertisement at the expense of staff and patients.
6. Under its sway professional standards applicable to the sick are more generally acknowledged and uniformly supported throughout the whole organization, both professional and lay, and alien creeds are not encouraged.
7. In making appointments to the staff the need of the hospital concerned is the only consideration and is paramount.
8. In it the factors productive of stress and strain to the staff are almost exclusively professional.
9. In it every specialism is considered a full-time job in itself; progress through the various stages of that specialism is better safeguarded, can be more accurately assessed, and its practice more effectively controlled and is moreover less likely to be involved in extraneous responsibilities.
10. Under the voluntary hospital system character is more uniformly an asset than a liability, and, in general, personal advantage is less likely to be at variance with professional duty.
11. In it local security of tenure is the rule and compulsory transfer of staff from hospital to hospital unknown.
12. The work of the ward sister is recognized as a life work in itself, and the possibilities of her contribution to hospital atmosphere, standard, and tradition are highly rated and fully acknowledged.
13. It provides opportunity, leisure, and rewards for its senior professional staff commensurate with their ability and position and in such manner as to stimulate progress.
14. It admits there are limits to the effective range of human control over others, and its practice is not suggestive of the dinosaur.

Virtues not all perhaps conspicuous by their absence in municipal systems, but conspicuously inconspicuous in some. The voluntary hospital arrangement is a pleasant, attractive, and effective system, with the path of honour eased and rendered even more attractive by a judicious use of limelight and the constant attentions of the mighty. Wise, too, for a job made easy is already half done. But freedom may become pathological and the enervating character of mutual admiration tend to smugness, especially when sequestered and aloof, protected from the buffeting endured by lesser breeds.

Time was in the tradition-forming days when the sole test for admission to the voluntary hospitals was the need of the

patient, and none was too dull, uninteresting, or unpleasant. Time was when character, religion, altruism, and untiring vocational nursing matched the present claims. For many years past, however, honour has gone where difficulties, other than technical, have been least—that is, to voluntary hospital staffs; public neglect and disdain have gone where the difficulties were greatest—that is, to the municipal hospitals. The levelling-up process (so called) proceeds apace in the municipal hospitals, however, though often with noticeable lag in municipal hospital enthusiasm, which quality was never greater, in my opinion, than in the years before 1929, when, though local difficulties were rife, they could be got to grips with and a generous meed of the above fourteen points was obtainable, and individualism, I fear, had scope. But that, of course, was making it much too easy. Incidentally, one notes that the medical superintendent casts his baneful shadow. Might one inquire if the comparable counterparts in the voluntary system are equally baneful, and, if so, are the hospitals so afflicted the least seaworthy? My name is not important, my pseudonym not.—I am, etc.,

Nov. 13.

"BEWARE THE POLITICIAN."

Surgical Instruments for Russia

SIR,—Surgical instruments of all kinds are urgently needed by the U.S.S.R., and at present it is possible for the manufacturers to supply only a limited number. Among the instruments required at once are:

Artery forceps of every description.	Bullet or swab forceps.
	Aneurysm needles.
	Surgical needle holders.
	Bone forceps.
Needles of all kinds (including intravenous, blood-transfusion, hypodermic, and spinal).	Scalpels and amputation knives.
Scissors of every description.	Plaster cutters.
Towel clips.	Tracheotomy tubes.
Dissecting forceps.	Abdominal retractors.
Aural forceps.	Volkman retractors.
	Sterilizers and autoclaves.
	Dental instruments.

The Anglo-Soviet Medical Committee appeals to all who have any surgical instruments which they can spare to send them as soon as possible to the Secretary, Joint Committee for Soviet Aid, 171, St. Stephen's House, Cannon Row, Bridge Street, London, S.W.1. The need is urgent, and instruments received will be dispatched promptly. Instruments which require to be re-plated or repaired will be accepted with gratitude, and will be restored to good condition before being forwarded to the U.S.S.R.—I am, etc.,

Nov. 24.

A. E. WEBB-JOHNSON,
President, Anglo-Soviet Medical Committee

R.M.B.F. Christmas Gifts

SIR,—Referring to my appeal on behalf of the Christmas Gifts Fund of the Royal Medical Benevolent Fund, I recently received a letter from a doctor aged 78. He and his wife, aged 72, are both beneficiaries of the Fund and their joint income is £169. They have been recipients of our Christmas gifts, and their letter states:

"As Christmas approaches we think of the special gift which the Committee has so kindly sent us for several years, but would like to make a suggestion. Since we came to this little farm worker's cottage we find expenses are easier than formerly. It would therefore give us much pleasure if our Christmas gift this year was given instead to someone who has been bombed out of home."

Many of our beneficiaries have unfortunately suffered through enemy action. May I, through your columns, ask those of your readers who have not yet responded to my Christmas appeal to send in their contributions as soon as possible to the Christmas Gifts Fund, Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, S.W.15.—I am, etc.,

THOS. BARLOW,
President.

Dec. 1

A pamphlet giving particulars of films dealing with physical recreation and health education has been published by the Central Council of Recreative Physical Training, 58, Victoria Street, London, S.W.1. The title of the pamphlet is "Films about Movement and Health," and it is priced 9d. post free. It should prove a useful guide to those arranging film shows in clubs, colleges, youth centres, etc.

Obituary

THOMAS CHARLES HUNTER, M.D.

The death occurred on November 15 of Dr. T. C. Hunter after a very short illness. He had spent nearly the whole of his professional life in Newcastle-upon-Tyne.

Thomas Charles Hunter was born at Sunderland on March 24, 1876, and was the second son of the late Sir George Hunter, the Tyneside shipbuilder. On leaving Fettes College he intended to become a shipbuilder and went abroad to complete his education. It was while he was in Spain that at the age of 19 he contracted pulmonary tuberculosis. He lived at Davos for the next two years and three more winters. His interest in medicine was now aroused, and at the age of 24 he had sufficiently recovered to begin the medical curriculum at Newcastle-upon-Tyne, where he qualified M.B., B.S. in 1904, taking the M.D. Durham in 1911.

He spent about a year in postgraduate study in Vienna, and for some time was an assistant in a practice at Consett. Then he settled in Newcastle in general practice. At one period he was assistant surgeon at the Children's Hospital, but his real interests were in medicine and diseases of the chest, and he soon confined himself to consulting practice. In the war of 1914-18 he joined the R.A.M.C., but after some months ill-health compelled him to resign his commission, and the rest of the war was spent in the country recovering. He was physician and later consulting physician to the Royal Victoria Infirmary, and also physician to the Chest Hospital in Newcastle. His great interest was the sanatorium for tuberculous children at Stannington, where he was visiting physician for about thirty years right up to the time of his death. Under his guiding influence this institution developed and flourished, and he wrote several papers on various aspects of the clinical work there. He had been a member of the British Medical Association for thirty-seven years.

Charles Hunter was intensely interested in his profession. He was a conscientious physician, deeply sympathetic towards his patients; indeed, his sensitive nature was perhaps rather too deeply moved by suffering and tragedy. He never sought the limelight, and was happiest with his family at his lovely cottage on the Durham moors, where he took a particular interest in growing roses. In his day he was a fine skater, a good lawn-tennis player, and a keen golfer. He never had robust health and had to live within his physical limits; but he faced life with great courage, gave of his very best to the community, and succeeded. His ready smile and warm-hearted friendship will be sadly missed by those who knew him.

G. M. GREIG.

H. O. WEST, M.D., F.R.C.P.

Dr. Henry Owen West, medical superintendent of Queen Mary's Hospital for Children, Carshalton, died on November 20 after a brief illness. He was a student of King's College and University College, London, and after graduating M.B., B.S. Lond. in 1909 served as house-surgeon at King's College Hospital and senior house-physician at the Seamen's Hospital, Greenwich. He proceeded to the M.D. in 1912, took the M.R.C.P. in 1914 and the D.P.H. two years later, and was elected a Fellow of the Royal College of Physicians in 1936. During the last war he held a temporary commission in the R.A.M.C., served as specialist sanitary officer, and was mentioned in dispatches.

A. T. sends the following appreciation:

By the untimely death of Dr. Henry West the London County Council has lost one of its most distinguished and popular medical superintendents. He was chosen by the Metropolitan Asylums Board to be superintendent of Princess Mary's Hospital for Children in 1919, having held several house appointments at King's, the Seamen's, and the Royal Chest Hospitals, and spent five years as tuberculosis officer in Kent.

Hackney, and Stoke Newington. When the L.C.C. took over the M.A.B. and Guardians' hospitals West was accorded the rapid promotion which his experience, ability, and qualifications warranted, and, after being in charge of the Archway and St. Giles general hospitals, was in 1937 chosen to succeed Dr. Gordon Pugh as medical superintendent of Queen Mary's Hospital for Children, Carshalton. This is one of the largest and best-known children's hospitals in the country, and Henry West, with his flair for quiet, happy efficiency, not only maintained but improved its standing. He was a man of great clinical and administrative ability: his outlook and method completely refuted the theory that the superintendent of a municipal hospital is a soulless bureaucrat with limited clinical knowledge and interest. West never ceased to be an ardent clinician, and one of the secrets of his success was that he could, and did, take a close personal interest in his juniors and in their clinical problems. His team at Queen Mary's was a happy one, and when, after the outbreak of war, E.M.S. personnel joined they were quickly incorporated as members. He was by nature a reserved man and no seeker after cheap popularity. He set a very high standard and was persistence itself in his demands for quality of staff and equipment and anything else that would improve his hospital. Of all his many fine qualities his innate genuineness stands out as possibly the most striking. His very arduous experiences of last winter may have predisposed him to the cerebral haemorrhage to which he succumbed. He never spared himself, and was proud that none of his patients suffered serious injury. The profession has lost a distinguished physician and the London County Council an outstanding officer. To his widow and his three sons our sympathy goes out in very full measure.

J. R. GILMOUR, M.B., C.M., F.R.C.P.Ed.

The sudden death of Dr. John Rutherford Gilmour on October 28 brought sorrow and a keen sense of personal loss to his many friends and former patients. Less than three years have passed since he left the post he had held for thirty-seven years in the West Riding of Yorkshire and retired to Overstrand, Norfolk, where he died.

Born in Edinburgh in 1871, and educated at George Watson's College, John Gilmour was a notable student at Edinburgh University, where he graduated M.B., C.M. with first-class honours in 1894. After holding a resident post in the Edinburgh Royal Infirmary and spending a short time in general practice, he joined Sir Thomas Clouston's staff at Morningside as an assistant physician, and so began his career in psychiatry. Becoming senior assistant physician under Dr. Rutherford at the Crichton Royal Institution, Dumfries, he remained there until 1901, when he was appointed by the West Riding County Council to direct the new mental hospital for private patients at Scaleshor Park, Burley-in-Wharfedale. He was medical superintendent of that hospital from its opening in 1902 until his retirement in 1939. He was elected a Fellow of the Royal College of Physicians in Edinburgh in 1902, and soon after taking up his post in the West Riding he married Miss Dorothy Rutherford, daughter of his former chief.

Although by nature reticent and unassuming, Dr. Gilmour's personality and ability soon made him a well-known figure in the West Riding, where, in addition to his other work, he had a large consulting practice. Of tall and distinguished appearance, he was gentle and kindly, calm, slow to anger, but quick to detect sham and hypocrisy, and always ready to maintain—against whatever odds—a cause he considered to be right and just. Scaleshor Park was his main interest, and the clinical side of his work there attracted him most. He had a shrewd insight into the nature of the problems of the mentally ill, and quickly gained the confidence and co-operation of his patients. Nothing was too much trouble for him and nothing too good for them. His memory was remarkable, and he could draw at will upon his large experience to point a moral or illustrate a case. He took an active part in the medical life of the West Riding, and regularly attended, and was an accomplished speaker at the clinical meetings of the British Medical Association and the Bradford Medico-Chirurgical Society. His fellow psychiatrists recognized his personal attributes no less than his stand-

ing in the specialty, when, in 1937, they elected him President of the Royal Medico-Psychological Association. He had been a member of the B.M.A. for forty-six years, and when the Association met at Bradford in 1924 he held office as secretary of the Section of Neurology and Psychological Medicine.

One of his oldest friends (T. B. H.), in the course of a tribute printed elsewhere, has written: "John Gilmour had a commanding presence. He invariably showed exceeding kindness to his patients and their relatives. His staff were well trained and devoted to him. He had a grand sense of humour. He had a happy home and was a delightful host. He was a charming companion on a holiday. He was a faithful friend, and those of us who knew him well missed the tall figure in the Inverness cape when he left the district. He never said an unkind word. He has left a fragrant memory of kindness, efficiency, and work well done."

One of the good old type of family doctors and general practitioners passed away at Bournemouth on October 23 in the person of JOHN ALFRED WARD, aged 77. Coming of Shropshire yeoman stock, he qualified from Guy's and then held some appointments at London public institutions. After that he went into practice at Grays, Essex, where he lived a very busy life for over twenty-five years. Those were the days when doctors had to tackle things somehow or other, before everything was rushed at once off to hospital, and when childbirth was looked upon as a physiological and not a pathological process. Neither did the general practitioner then get those pleasant breaks in the drudgery such as half-days for golf and regular evenings off. Ward was plunged into a most strenuous life with a large practice and constant midwifery in a poor neighbourhood. He was also one of the honorary surgeons at Tilbury Hospital, medical officer of health for Grays Urban District, and medical officer to the training ship *Shaftesbury* in the River Thames. Despite all this he had the grit to take the degree of M.D. Durham for practitioners of fifteen years' standing. This necessitated doing a book of Caesar, and the writer has a vivid remembrance of an early morning visit to Ward's house and finding him half dressed, after a maternity night-out, trying to do morning surgery, eat some belated breakfast standing up, and construe some Caesar, all three efforts being intermingled! We finished the Caesar together, but that little vignette gives an idea of the full life he lived. At this pace, no wonder if he was tired. Fortunately he was able to give up general practice fairly early. He then spent some years as ship surgeon with the P. & O. line, and was able to visit Australia and the Far East. Being unmarried, he had no family responsibilities. He finally retired to live quietly at Bournemouth. A pleasant aspect of his personality was the country farmer element, which he retained through life, with interest in the land, crops, shooting, etc., though he never got much time off to indulge in the last. These few memorial lines are offered by one who was in keen competition with him during that quarter of a century of practice, as a respectful testimony to a genial and quiet personality. *Molliter ossa cubent.*—A. F. B.

We regret to announce that Dr. ALFRED LINNELL died on November 18 at his home in Northampton at the age of 60. The son of J. E. Linnell of Paulerspury Hill, he studied medicine at Guy's Hospital, where he played in the Rugby Cup-tie XV, and qualified as M.R.C.S. in 1883. He returned to his birthplace to work in general practice there, and took a prominent part in the public life of the district. When the Northamptonshire Insurance Committee was set up in 1913 he represented his parish on that body and served for two years as its chairman. In 1920 he was appointed regional medical officer under the Ministry of Health and went to live first at Northampton, then at Leicester, and on his retirement returned to Northampton. Dr. Linnell joined the British Medical Association fifty years ago. He had been president of the South Midlands Branch in 1910, and was a member of the Rural Practitioners Subcommittee 1911-20. He served on the Consultative Council for Medical and Allied Services which was set up by Lord Addison as first Minister of Health, with Lord Dawson as its chairman, but resigned on appointment to the staff of the Ministry.

A correspondent writes: Those who knew Alfred Linnell will treasure his memory as one who was a splendid type of rural practitioner. Great in stature, robust in body and mind till an advanced age, he was a man who inspired confidence. He excelled in open-air sport as a young man. He loved the country and understood it. Kindly, shrewd, and reliant, it is little wonder that he built up a good practice at Paulerspury, the village where he was brought up. He took an active part in parish and Church affairs and was held in high esteem by everyone who knew him, particularly by his patients and professional brethren. He was constant in his attendance at medical meetings and could always be relied on to give a sound opinion, expressed in a clear and definite manner. He was recognized as one whose views on medico-political matters were most valuable. When the National Health Insurance Act came into being Linnell was the inevitable choice as representative of his district, and he became one of the first members of the Insurance Acts Committee. Here his talents were properly valued, and when regional medical officers were first appointed he was among the chosen. No one was more suitable. He had a wide knowledge of medical practice and of human nature, which enabled him to hold a fair balance when there were differences between his Department and medical practitioners. It is a tribute to the democratic ways of our Association that a man who started his professional work in a village practice could attain to the position he held—not only his official position but the place he held in the hearts of his fellow-practitioners.

Dr. DAVID ROBERTSON TAYLOR died on November 8 at his residence in Malone Road, Belfast. He was educated at the University of Edinburgh and Queen's University, Belfast, graduating M.B., Ch.B.Ed. in 1906 and taking the Belfast D.P.H. in 1918. He had held the posts of house-surgeon at the Royal Victoria and the Maternity Hospitals at Belfast. Dr. Taylor was a member of the British Medical Association and the Ulster Medical Society. He was an old-established general practitioner of the classical type, and during the present war was constantly engaged on medical boards. He was an outstanding athlete and represented Ireland at rugby football as a centre three-quarter in 1903. In more recent years cricket commanded his attention, and he represented the Province of Ulster on many occasions.

Dr. PETER MURRAY KERR died on November 16 at Dumfries at the age of 78. He was one of the best-known doctors in the south of Scotland, where he had practised for nearly half a century. He took the M.B., C.M. at Edinburgh University in 1887, and not long after graduation settled in Dumfries, where he served for many years as surgeon to the Dumfries and Galloway Royal Infirmary. Dr. Kerr joined the British Medical Association in 1892, represented the Dumfries Division at the Annual Meeting of 1908, and held office as chairman in 1925-6; in the following year he was elected president of the Border Counties Branch. In his early years of practice he had been medical officer to the old Dumfries Parish Council; later he served for twenty years as medical referee for Dumfriesshire under the Workmen's Compensation Act and for the Ministry of Pensions. He joined the 3rd King's Own Scottish Borderers in 1891, and was gazetted to the command of the 5th Battalion in 1911. He went with his regiment to Gallipoli in 1915 with the rank of lieutenant-colonel, but was invalided home. After the last war he maintained his keen interest in the regiment as its honorary colonel, and received the Territorial Decoration. In 1930 his services to the local hospital and to the community of Dumfries and district were publicly recognized. In recent years he had been an honorary Sheriff-Substitute, and also a J.P. for the county.

The following well-known medical men have recently died abroad: Dr. DEAN DE WITT LEWIS, president of the American Medical Association, 1933-4, editor from its foundation of the *System of Practice of Surgery* and of the *International Surgical Digest*, and editor of the *Archives of Surgery* since 1921; and Dr. FRANK BURR MALLORY, formerly professor of pathology at the Harvard Medical School, Boston, editor of the *American Journal of Pathology*, and co-editor with J. Homer Wright of *Pathological Technique*.

Medico-Legal

A FATHER'S DILEMMA Refusal to allow Amputation

A labourer of Glamorgan, an ex-soldier with six children, was tried recently at the local quarter sessions for neglecting one of his sons, aged 6 years, by failing to provide him with adequate medical attention. The evidence for the prosecution was chiefly medical and was not substantially in dispute. The boy was suffering from tuberculosis of the left knee. He had been in the special hospital at Glan Ely for fourteen months and had been discharged able to walk. In April of this year, however, he was readmitted; his condition was steadily getting worse and he was beginning to suffer from chronic general poisoning. The medical men in charge of the boy advised the father that the only hope for the boy's life was to amputate the leg, and that even this, in view of his bad general condition, would be a dangerous operation. The father refused his consent, and the prosecution followed. Council for the defence said on the father's behalf that he had not been told his son's life was in danger and that he had not finally, but only provisionally, refused consent. The man himself said he was afraid the shock of the operation would kill his son; that during his service through the last war he had seen a great many fatal amputations; and that if he thought the child would recover he would consent at once, though even so the child would be a cripple for life. The jury acquitted him after only two minutes' deliberation in open court.

Considering that the prosecution admitted a substantial risk that the amputation might not save the boy's life, it is a little difficult to see why the authorities should have seen fit to add to the father's existing distress and anxiety by prosecuting him. Medical attention is a "necessary" for the provision of which a minor may make a valid contract, and which the parent or guardian of a minor is bound by law to provide. This obligation has probably always existed at common law, but has been specifically enacted in a number of statutes relating to the welfare of minors. The law at present in force is contained in Section 1 of the Children and Young Persons Act, 1933. It is a criminal offence to neglect a child under 16 in a manner likely to cause him unnecessary suffering or injury to health, including injury to or loss of sight, hearing, a limb, or an organ of the body. A parent or guardian is deemed to have neglected a young person under this section if he has failed to provide adequate medical aid for him, or failed to take steps to procure it to be provided under the Acts relating to the relief of the poor.

Did the Parent Act Reasonably?

The present case is amply covered by authority. In *Oakey v. Jackson*¹ a girl of 13 had been suffering from adenoids, which were injuring her health. The only possible remedy was a surgical operation. This was not a dangerous operation, but the father refused his consent to it. He was summoned for wilfully neglecting her in a manner likely to cause injury to health, by failing to provide adequate medical aid (the Children's Act, 1908, contained the same provisions as the 1933 Act). The justices dismissed the information on the ground that the father was under no legal liability to consent to the operation. Mr. Justice Darling said on appeal that in such cases, as in so many other branches of law, the test must be whether or not the parent has acted reasonably. There may, he said, be cases in which a parent is bound to allow his child to undergo an operation, but a refusal to allow an operation is not necessarily a failure to provide adequate medical aid of a kind which offends against the statute. The question can be answered only by considering all the evidence in each case; it is one of fact. The justices who are called upon to reach such a decision must take into consideration the nature of the operation and the reasonableness of the parents in refusing to permit it. Mr. Justice Avery added that another material fact is whether the operation is advised by a qualified medical practitioner or merely by some irresponsible person. In the case against the Glamorgan father the chairman of the sessions, following this decision, put to the jury the

simple question: Was the father's refusal reasonable in all the circumstances? and the jury had little hesitation in finding that it was.

A correspondent has asked whether in such a case a court has power to order a given operation to be performed. The answer seems to be clearly laid down in the 1933 Act, Section 63. If the jury acquits, the court of course takes no notice of the order, but if the parent is convicted the court may make an order committing the child to the care of a "fit person." Often the fit person is the local authority, and under the order it has the powers of a guardian to give consent to the indicated operation. Alternatively, the court may bind the parent over to exercise proper care and guardianship, and this would presumably include his consent to the operation.

The Services

NAVAL AWARDS

The D.S.C. has been awarded to Temporary Surgeon Lieuts. Emlyn Roderick Llewellyn Davies (H.M.S. *Manchester*), Cyril Joseph Vaughan (H.M.S. *Forester*), and Eric John Yates (H.M.S. *Fearless*) for courage and resolution in operations in Mediterranean waters.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

War Substantive Captain ERNEST JOHN FRANK HINDE, who was announced as "Missing at Sea" in the *Journal* of November 1 (p. 638) and who is now reported to have died at sea in August as the result of enemy action, was the eldest son of Dr. and Mrs. E. B. Hinde of Norwich and qualified M.R.C.S., L.R.C.P. in 1938. In October, 1939, he was granted a temporary commission as lieutenant in the R.A.M.C., and was promoted captain a year later. He was a member of the British Medical Association. He leaves a widow.

Missing

Lieut. Niall Eugene O'Neill (not prisoner of war, as announced in the *Journal* of November 16, p. 639).

Prisoner of War

Lieut. John Edward Readman.

Universities and Colleges

UNIVERSITY OF EDINBURGH

At a meeting of the University Court, held on November 17, with Sir J. Donald Pollock, Rector, in the chair, it was reported that Dr. H. M. Traquair had been appointed a member of the Court as a General Council Assessor in succession to Sir Norman Walker.

On the recommendation of the Senatus and the Faculty of Medicine, the Court approved the appointment of Prof. Bruno Nowakowski, professor of hygiene, as a member of the Faculty of the Polish School of Medicine in Edinburgh.

It was announced that a bequest had been received from the late Mrs. M'Laren of Stirling of £2,000 in memory of her husband, Lawrence M'Laren, the interest to be used for research in the cause and cure of brain and nerve trouble and to be called the Lawrence M'Laren Bequest.

EXAMINATION FOR CZECH MEDICAL DEGREES

At the request of the Czechoslovak Minister of the Interior and Education in London, the Examining Board in England of the Royal Colleges of Physicians and Surgeons has undertaken to conduct a special Final Examination (Second and Third Rigorosa) for the Czechoslovak MUDr. degrees. Part I (Pathology and Bacteriology) was conducted in London last week, when twelve candidates were examined, of whom the following satisfied the examiners: Artur Flach, Jan Glaser, Zdenek Pfeifer, Karel Skopek, Karel Josef Susat, Walter Tausig, Josef Voracek, and Josefina Liebssteinova.

Medical Notes in Parliament

Health and Disease in the Colonies

Mr. NOEL BAKER opened, on November 20, a debate on colonial affairs. He said Parliament was now building up the social services of the Colonies, but there was still too much poverty and preventable disease. Mr. DE ROTHSCHILD said that under the Colonial Development Act the production of subsistence crops should be encouraged. There was much chronic ill-health among the natives due to a diet of low nutritive value. Unless a deficiency of sound home-grown food was remedied the work of doctors, nurses, and hospitals stood little chance of success.

Dr. MORGAN said the people of the West Indies suffered from malnutrition because the ground was used for exportable crops. There were in the West Indies instances of a chief medical officer acting on a basis of favouritism and of crowds of doctors moved without cause to the poorest parishes. He found the people of the West Indies living in a cesspool of disease—yaws, hookworm disease, syphilis, malaria, tuberculosis, infectious diseases, leprosy. Tuberculosis in the West Indies was of a galloping type, and in certain places syphilis affected 60% of the population. Hookworm disease spread because the Government would not insist on preventive measures. The doctors were blamed for a medical policy with which they had nothing to do. He had never seen a more disgraceful hospital than at San Fernando in Trinidad.

Mr. GEORGE HALL replied to the debate, but did not deal in detail with Dr. Morgan's charges.

High-frequency Apparatus

On November 27 Mr. HERBERT MORRISON told Dr. Howitt that for security considerations he could not instruct the chief officers of police to report on the possibility of licensing the use of more short-wave high-frequency apparatus, such apparatus being completely screened and issued only to practitioners for whose integrity the police could vouch. This proposal, he added, had been considered before the Control of High-frequency Apparatus Order was made. Dr. HOWITT asked whether a test had been made of how far these rays travelled. Mr. MORRISON replied that he could not say. It was undesirable to discuss such details in public.

Diphtheria Immunization.—On November 18 Mr. VIANI asked the Minister of Health whether he would obtain information of the amount of immunization against diphtheria practised in the areas covered by his circular dated June 12, 1941, in view of the fact that unless this information was given the mere number of cases of diphtheria notified and the proportion of cases immunized would not have any significance. Mr. ERNEST BROWN replied that the main purpose of the returns referred to in the circular was to furnish information about the extent to which immunization of children against diphtheria was carried out between January 1, 1940, and September 30, 1941. The return had been asked for from all local authorities.

Disease in Wiltshire Labour Camps.—Sir PERCY HURD inquired on November 20 what action Mr. Brown had taken upon the report last month by the Wiltshire Public Health Committee that the committee had been called upon to provide facilities for cases of vermin, scabies, venereal disease, and advanced pulmonary tuberculosis among imported labourers, especially from Ireland, for employment on Government contracts. Mr. BROWN reported local consultations with all concerned regarding medical arrangements at the labour camps referred to. The county council's medical officer was giving valuable assistance, and the necessary measures were in train.

Sir PERCY asked whether steps would be taken to ensure a strict medical examination before importation of labour. Mr. BROWN said that point was being considered in conjunction with the Ministry of Labour and National Service.

Compensation for Shock.—Sir WALTER WOMERSLEY said on November 20 that his attention had not been drawn to a decision given in the Bristol County Court that injury under the Personal Injuries Scheme did not include shock unless accompanied by physical injury. He added that compensation was payable where, as a result of enemy action, a person sustained concussion of the brain, whether there was visible injury or not, or where a person sustained nervous shock of a commotional character associated with blast, burial among debris, or some similar severe incident. In either case the patient must be medically certified as incapable of work.

Incidence of Tuberculosis among Young Women.—On November 20 Mr. BROWN told Mr. J. Griffiths that in 1940 mortality among women from all forms of tuberculosis showed an increase of 11% over the figure for 1939. The highest incidence was in the age group 20-24, where the increase was 18%. He had arranged, with the co-operation of the Medical Research Council, for expert investigation of the possible causes of the increase. Everything possible was being done to maintain the tuberculosis service.

Insurance Practitioners: War Bonus.—On November 25 Mr. ERNEST BROWN said that he had received copies of resolutions recently passed by the Doncaster and Kent Panel Committees supporting the appeal for a war bonus of 4s. to insurance practitioners. He could not see his way to grant such a bonus.

Mr. GROVES asked whether the Minister was aware of the difficulties of the average medical practitioner to meet the increased income tax out of a capitation fee which, despite its rise, really remained as it was at the end of the last war, and whether he would consider granting a war bonus. Mr. BROWN: I am not aware of any reason why medical practitioners should not be subject to income tax in the same way as other citizens. The capitation fee is to be increased for other reasons from the beginning of next year, and I am not prepared to increase it further by way of compensation for the increase in income tax.

Pediculosis, etc., in Evacuated Children.—On November 25 the Minister of Health was asked whether he was aware that the condition of evacuated children from London showed pediculosis, impetigo, and scabies, and why such children were permitted to change their residence. Mr. BROWN said he was aware that in the past children suffering from these conditions had sometimes arrived in the reception areas. It had recently again been thoroughly impressed on the evacuation authorities in the London area that before organized parties of children were sent to reception areas medical inspection must be carried out and, where necessary, the children must receive efficient treatment before they might travel. The authorities knew that no child who was suffering from an infectious condition must be sent out until he was cured.

Courses for R.A.M.C. Officers.—On November 25 Captain MARGESSON, replying to Mr. Thorne, referred to courses given to civilian doctors on entering the Army Medical Service. He said that some 5,000 medical officers had passed through a course at the Army School of Hygiene, and over 1,000 through a course for the treatment of mechanical warfare casualties.

Notes in Brief

On November 25 Captain Margesson told Mr. Leach that no cases of small-pox in the Army had been reported since the outbreak of war.

Major Lloyd George states that, provided they are stored under suitable conditions, canned foods such as are now being distributed remain sound indefinitely.

Major Lloyd George stated in reply to Captain Profumo that no recommendation made by the Medical Research Council with regard to national wheatmeal bread had been rejected by Lord Woolton. All had been acted upon, with one exception. That is still being examined.

The November issue of *Industrial Welfare and Personnel Management*, the journal of the Industrial Welfare Society, includes an article on Factory War Casualties by Dr. H. A. Faulkner, who describes the need for "a carefully planned bomb-proof organization to deal with the results of incidents," and outlines the principles on which the scheme in his firm is run: competent area first-aid organizations under efficient incident officers; central mobile units of well-trained first-aiders for use in any part of the works; a well-equipped casualty clearing station (with equipment for comfort of patients as well as medical and surgical treatment), and one or more reserve casualty clearing stations. An editorial discusses means for controlling influenza and the common cold, which are responsible in normal times for between 30% and 40% of the working hours lost in industry. Firms are trying various methods in the hope of reducing this loss: free inoculation of employees, sun-ray treatment, distribution of vitamin capsules, reduction of overcrowding, encouragement of the use of face-masks, spraying the air with disinfectant, education in general hygiene by works doctors and nurses. A letter from Dr. T. E. A. Stowell, chairman of the Industrial Welfare Society's advisory medical committee, points out the dangers of unsupervised use of artificial sunlight treatment, but emphasizes the value of correct exposure in preserving health, promoting a sense of well-being, reducing fatigue, and increasing resistance to disease.

SURVEY OF LONDON HOSPITALS

In the House of Commons on Tuesday Captain G. S. Elliston asked the Minister of Health whether he was in a position to make any further statement about the survey of hospitals in London and the surrounding area proposed in connexion with the Government's post-war hospital policy. Mr. Ernest Brown, in reply, gave the following as the terms of reference for the guidance of those undertaking the inquiry:

"To survey the hospitals (other than mental hospitals and mental deficiency institutions) in London and the surrounding area; and having regard to the information thus obtained and to the general principles of post-war hospital policy laid down by the Minister of Health in the House of Commons on October 9, to advise the Minister what area would appropriately be served by a hospital system centred on London, and what modifications or extensions of the existing hospital facilities would be necessary or desirable to give effect to that policy."

The Minister added that he had invited Dr. A. M. H. Gray, President of the Royal Society of Medicine, and Dr. Andrew Topping, Deputy Medical Officer of Health and School Medical Officer for the County of London, to act as surveying officers, and both had accepted the invitation. The services of Dr. Topping had been made available through the kind offices of the London County Council. A beginning had already been made with the preliminary work of the survey.

While it happens that one of the "surveyors" is associated with the voluntary hospitals and the other with the municipal, it is understood that they have not been chosen as representatives of these two aspects, but merely as persons who have had large experience in separate fields of hospital administration. The business of Dr. Gray and Dr. Topping will be to advise as to how hospitals can give the best service to the public; we understand that the whole question of teaching would be considered separately.

Medical News

At a meeting of the Pharmaceutical Society of Great Britain on Thursday next, December 11, at 2.30 p.m., in the Society's house, 17, Bloomsbury Square, W.C., the Harrison Medal will be presented to Mr. Thomas Tickle, B.Sc., public analyst for the County of Devon, and a member of the British Pharmacopoeia Commission. After the presentation Mr. Tickle will deliver the Harrison Memorial Lecture on "The Influence of Analytical Chemistry on Pharmacy." In this he will give the impressions of one who was first trained as a pharmacist and who afterwards practised as an analyst for forty years in close association with pharmaceutical matters. It is hoped that members will bring friends. Tea will be served after the meeting.

Colonel T. E. Osmond will deliver a lecture on "Venereal Disease in the Army: its Prevalence, Prevention, and Management," at the Weston Hotel, Bath, on Thursday, December 11, at 5.30 p.m. All Service medical officers and civilian practitioners will be welcome.

Mr. Ernest Brown, Minister of Health, will address a meeting on December 10 at the Royal Institution, Albemarle Street, under the auspices of the National Council for Maternity and Child Welfare. His subject will be "The Care of Mother and Child in Wartime." The other speakers will be Miss Crosbie and Professor Fletcher Shaw. Lord Dawson of Penn will preside. Dr. Allen Daley, Chief Medical Officer of the L.C.C., will propose, and Dame Louise Mellroy will second, the vote of thanks.

A Dominions and Colonies Section meeting of the Royal Society of Arts will be held at John Adam Street, Adelphi, London, W.C., on Tuesday, December 16, at 1.45 p.m., when Dr. Maurice Ashby will read a paper on "British Empire Drug Production."

Owing to the efforts of the Nazis to secure medical aid for the war wounded in Slovakia, cars have been sent to the Jewish internment camps and forced labour battalions not only for Jewish doctors but also for male nurses and medical students.

The Minister of Health announces that the Medical Research Council has tested samples of pituitary extracts carrying the expiry date October 26, 1941, and has reported that provided supplies of these extracts have been kept under ordinary conditions of storage and at normal room temperatures they may be used with safety for a further twelve months.

The well-known firm of manufacturing chemists in the United States, John Wyeth and Brother, Inc., of Philadelphia, recently restored the old necropsy house of the Philadelphia Hospital at Old Blockley, and dedicated it to the memory of Sir William Osler. In the June issue of the *Bulletin of the History of Medicine* there are fifty pages to commemorate the dedication of the Osler Memorial Building. This interesting and profusely illustrated section includes a number of signed articles bearing upon Osler's life, with special reference to his years at Philadelphia as professor of clinical medicine in the University of Pennsylvania.

The September issue of the *Journal of Pediatrics* is devoted to the problems of adolescence.

EPIDEMIOLOGICAL NOTES

Discussion of Table

An increase in the notifications of pneumonia, dysentery, and whooping-cough occurred during the week in England and Wales, the notifications of the other infectious diseases being below the totals of the preceding week. The large rise in the incidence of pneumonia—266 cases—was distributed throughout the country.

A further 65 cases of measles were notified in the epidemics which began during the previous week in Kent, Easby R.D., with 94 cases, and an outbreak of 20 cases in Malling R.D. was also reported from that county. Four of the 21 cases of poliomyelitis were recorded in Buckinghamshire: that county is again the principal centre of infection, a position it occupied three months ago, when the incidence of this disease started to rise.

In Scotland a fall in the number of notifications of diphtheria, measles, and dysentery was recorded, while the figures for scarlet fever, whooping-cough, and pneumonia were in excess of the totals of the preceding week.

In Eire the notifications of diphtheria, measles, and whooping-cough were twice as numerous as in the previous week. Whooping-cough was practically confined to one area—Westport R.D. Co. Mayo, where 49 of the 57 cases were notified. The largest rises in the figures for the other two diseases were recorded in Dublin.

Diphtheria

The number of cases of diphtheria notified in England and Wales was 26 fewer than in the preceding week. During the past two months the weekly total of notifications has alternately risen and fallen, and there has been no obvious tendency towards an increased or decreased incidence for the country as a whole. The trend of the notifications in the various divisions of the country has, however, not been uniform, and some interesting contrasts are displayed when the subdivisions are considered. In Wales there has been a 50% increase during the past three months; in the north-western counties the increase has been of the order of 25%, while in the south-western counties the incidence has declined by 50% during this period.

Dysentery

Notifications of dysentery in England and Wales increased by 56 during the week compared with the total of the preceding week. The largest of the local outbreaks was reported from the administrative areas of Surrey (Coulsdon and Purley U.D. 19, Dorking and Horley R.D. 12), Dorset (Dorchester R.D. 10), Derbyshire (Derby C.B. 22), and Lancashire (Blackburn R.D. 19).

Returns for the Week Ending November 22

The returns of infectious diseases notified during the week included scarlet fever 1,417, whooping-cough 1,995, diphtheria 1,082, measles 639, pneumonia 1,100, cerebrospinal fever 114, poliomyelitis 13, dysentery 209, paratyphoid 18, typhoid 10. Deaths from influenza numbered 25.

No. 46

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 15.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. *Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for:* (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

QUERIES AND ANSWERS

Stabbing Heel Pains in Rheumatoid Arthritis

Dr. E. S. HART writes from Great Yarmouth in reply to W. R. S., whose query appeared on November 15 (p. 716): Has the patient tried raising the bedclothes with a stool?

Gum of Postage Stamps as Germ Carrier

Mr. A. ERNEST SAWDAY, F.R.C.S.Ed. (London, N.8), writes: For the greater part of my life I have collected stamps. This hobby is very popular among medical men. If this note should catch the eye of a philatelic bacteriologist his observations as to the possibility of tubercle bacilli (and other organisms) being carried alive in the gum of postage stamps would be of interest.

Students Seeking Midwifery Cases

PAUL A. RIDDLE, GORDON D. McDONALD, and DIXIE M. CLEMENT write from the Edinburgh University Union: We are three fourth-year medical students of Edinburgh University at present attending midwifery lectures. We would like to do our twelve practical midwifery cases from the same hospital during our Easter vacation (March 19 to April 14). We would be very grateful if any of your readers could put us in touch with any hospital or institution which would be willing to take us, together with details of cost, etc.

Income Tax

General Practice and Appointments

J. O. is in general practice and also holds two or three appointments, for one of which—part-time M.O. at a factory—he receives £450 per annum. Must the emoluments from these appointments be assessed under Schedule E?

* Strictly such emoluments are so assessable, but it is the general and accepted practice of the Inland Revenue Department to include them in the general receipts of the practice where the duties are of the ordinary professional type. That condition seems to be met in J. O.'s case, and we think that his request for assessment under Schedule D only is in accordance with general custom. If the local inspector of taxes does not agree we suggest that the facts be put before the Chief Inspector of Taxes, Somerset House, London, W.C.2.

LETTERS, NOTES, ETC.

Control of Scabies

Dr. W. F. COOPER writes: There have been letters which, very rightly, emphasize that a proof of cure is difficult. I wrote (April 19, p. 616) stating from personal experience that sulphur alone (and it is necessary to emphasize that it is mixed with nothing whatever) was efficacious. When I was abroad a friend who was staying with a neighbour some five miles off came to me suffering from itch. In a few days I also was infected. I treated this man and myself by dusting powdered sulphur into our clothes, into the rugs (no sheets), and all over the joints of the iron bedstead. I used the same clothes every day, partly because we had only one or two spares, partly because I knew that it would not matter. I had a bath at night as usual, and changed into pyjamas, which were also thoroughly dusted with sulphur. In a country where one gets very hot there is no possible doubt whether one is itching, and so a cure of "itching" can be quite certain. After a few days of this powdered sulphur treatment there was no more itching; so if the acarus remained it had lost all power of causing trouble. There was no return of it over a period of several

months. It is well known that sulphur is one of the most effective remedies against pests, and has been used for centuries. Many thousands of tons of it are used annually in other parts of the world against both insect pests and fungous diseases. The most usual form is as calcium polysulphide, which is a solution of sulphur in calcium hydrate. On exposure to air this forms chalk and the sulphur is precipitated. If the shelters were sprayed out with this solution (diluted) there would be no infestation of the places by "itch," and infectious diseases should be reduced.

The Future of Mental Health

Dr. F. DUDLEY (Newton Abbot) writes: I have read with interest and appreciation Dr. A. J. Brock's comments (November 15, p. 710) on Dr. Karin Stephen's article which appeared in your issue of October 25 (p. 589). The difficulty is to find the "mentally healthy milieu" in which to treat suitable cases. There are psychoneurotics who, when admitted to a mental hospital, at once begin to improve. Mental disability is, if possible, even more widespread than physical disability, and, like it, is a matter of degree. Reason and emotion are more often than not incompatible. There is more unreason outside the mental hospitals than in the wards. The certified patients are those who, because of their disability, are incapable of looking after themselves or managing their affairs, and whose friends are unable or unwilling to do so. There are mentally unbalanced dominant personalities whose conduct makes the lives of relations and friends a misery, but the latter, for family or other reasons, will not have them "put away."

Treatment of Burns and Wounds by the Envelope Method

Dr. D. O'DWYER (Plaistow, E.13) writes: I was surprised to read in the letter of Mr. A. G. F. Halford (November 22, p. 750) certain criticisms of the envelope treatment for burns. In his reference to Lister there was the following statement: "He contended that antiseptics, however mild, interfered with healing. . . ." Is it presumptuous to suggest that if the great man were alive to-day he might be prepared to qualify this statement? With regard to eusol, my experience over a period of twenty-five years has been the reverse of this contention. Whatever the faults of this antiseptic may be, I don't think that anyone would maintain to-day that it interferes with the healing of wounds. The beauty of the envelope technique is that it minimizes any objectionable features in the hypochlorite solution, while utilizing to the full its healing and antiseptic properties. It has been made clear that the action of electrolytic sodium hypochlorite is not so much in killing germs as in removing necrotic tissues.

Malaria illustrated by Cinematograph Film

Dr. P. A. STEVEN (Ripon) writes: I was interested to read in the *Journal* of November 15 (p. 707) of a film on malaria, and trust some day the profession may have a chance of seeing it. I see the idea is a world-wide production. The description is thrilling, and to those of us who in the late war served in malarial districts is of special interest. I trust we in time may have the pleasure of seeing the production.

Clothing Coupons for the Expected Child

Dr. N. KEMP (York) writes: I suggest that an effort should be made to secure an alteration in the regulations for the supply of coupons to the expectant mother for the necessary clothing for the expected child. The supply appears to be quite inadequate. One of the principal grievances is that for each napkin made of Turkish towelling one coupon is required. An experienced maternity home matron, who can look back upon a long succession of patients to whom she has been in the habit of giving detailed advice about the equipment of the infant, tells me that thirty-six napkins are necessary. Thus, straight away thirty-six coupons have to go. It is true that for the various kinds of muslin squares no coupons at all are asked. They, however, are more expensive and much less "thrifty," being less able to stand the perpetual washing required. Fourteen coupons are left, therefore, for the other items of clothing, and the child requires at least two of each garment, and should have three. It is difficult to see how the child can be fitted out with fewer than sixty coupons, especially in the case of the less well-to-do. If the infant is not the first arrival in the family, no doubt the time-honoured custom of the younger members wearing the cast-off clothing of the older ones is a help. Further, apparently in some areas these coupons are not to be given before the sixth month of pregnancy. This leaves much work to be done by the expectant mother at a time when she might be glad to think by her preparations were nearly completed. A further strange direction in some of these cases is that the expectant mother is called upon to attend at an office at some considerable distance from where she lives in order to procure the coupons, and this at the sixth month of pregnancy, and in these times when travelling any distance is not encouraged.

OBSERVATIONS ON SOME NORMAL AND INJURIOUS EFFECTS OF COLD UPON THE SKIN AND UNDERLYING TISSUES

II. CHILBLAINS AND ALLIED CONDITIONS*

BY

SIR THOMAS LEWIS, M.D., F.R.C.P., F.R.S.

Physician to University College Hospital

The reactions of the skin to cold described in Lecture I (p. 795) are acute reactions in that they appear in quick response to the stimulus and are relatively transient effects. The main response is vascular, consisting of vasodilatation and increased permeability, displayed in the traditional signs—redness, heat, and swelling. We are about to examine reactions that are neither transient nor so simple, and yet are recognized as associated with exposure to cold. And we are to discuss the responsibility of cold for these lesions and the manner in which they are produced. I refer to chilblain, to "erythrocyanosis" of the skin, and to so-called "trench foot."

Principal Features of the Lesions

First it may be well briefly to outline the salient features of these lesions and the circumstances in which they arise.

Chilblain.—The chilblain is most familiar to us as it occurs on the fingers, its most frequent site. It affects particularly the dorsal surface of the phalanges, especially between rather than over the joints. The thumbs are relatively exempt, though there is no part of the dorsal surface of the hand, or for that matter of the foot, which may not be affected. The chilblain appears as a red swelling, usually warm or hot and itching. There is obvious vasodilatation, and there is oedema—phenomena which, like itching, are common reactions to cutaneous injuries of any kind. The further course of the chilblain is inconstant. It may disappear in a few days. Usually it continues for periods of days, weeks, or months, but the original state of vasodilatation subsides. Redness gives place to a deep purple or reddish-purple colour, itching to soreness and pain; the swelling remains and may increase; the tissues may become tender; the skin often blisters or even ulcerates; but whichever happens the inflammation tends to indolence and slow healing.

That chilblains have come to be regarded as provoked by cold, and not by frost, is implicit in a term that has for so long met with popular approval in this country. But in other lands cold as the essential provocation has not been so clearly recognized. Thus it happened that Unna (1894) obtained credit for asserting, as late as that time, that these lesions, popularly termed "Frostbeulen" in German-speaking countries, are not due to freezing, as he stated they were generally regarded to be. The chilblain is common in our own land, where, though damp cold is frequent, frost-bite is a rarity. It appears with winter and generally departs only with the coming of warmer days. It is not the rule for subjects to account for the lesions presented by a single and unusual exposure to cold, though from time to time such histories are given. It is quite definitely the rule that sufferers from chilblains of the hands are people, young rather than old, whose hands in winter, and quite often in summer too, are habitually colder than those of their companions. It often happens that the hands as a whole are deeply coloured.

Erythrocyanosis of the Leg.—This lesion appears as a vascular discoloration of the lower part of the leg; the front of the leg immediately above the ankle is perhaps the favourite site. The skin becomes diffusely purple, or purple and red; the region of the follicles is often particularly marked by this congestion. The skin is usually over-tense, and therefore sometimes shiny; the oedema may be great, and in time the skin may blister or thickening may appear and break down to form ulcers. The lesions become chronic and indolent, and breaches of the skin surface heal slowly. The relation of the lesion to cold is similar to that of chilblain. It comes in winter and stays till the warmer days return. As in the case of chilblain of the hands, with which it is often associated, this lesion appears in those whose limbs tend to persistent coldness.

Trench Foot.—This condition sometimes begins with pain and tenderness without notable abnormality in appearance. Usually the foot is cold, red or blue, and swollen. Out of the cold trench the foot may be hot. In the more severe cases blisters and ulcers form and areas of the skin become necrotic; toes or even large parts of the foot become gangrenous. The condition was recognized and clearly described by Larrey (1812) in his account of Napoleon's Russian campaign. Larrey's description is memorable: he pointed out that the malady could not be ascribed to frost-bite. He says that in the exceedingly cold days which preceded and succeeded the Battle of Eylau—the temperature being 10° to 15° (Réaumur) below zero (9.5° to -1.75° F.)—not a soldier complained of frost-bite, although the days and many of the nights were passed in the snow with hard frosts. Then the temperature rose abruptly to 3° and 5° R. above freezing-point (39° and 43° F.); a thaw had set in and it rained. From this time a large number of soldiers complained of severe pain in the feet, and of itching, redness, and swelling, which progressed in some to insensibility and gangrene. In the Crimean War the most serious foot troubles appeared in cold wet weather. In the war of 1914-18 "trench foot," as it was called in France, appeared among men who stood or worked for days in the cold water or mud of the trenches, and was responsible in the first winter for thousands of casualties (Grattan, 1922, 1923). Similar foot trouble was reported among Turkish soldiers exposed in wet cold trenches (Wieting, 1913). By general consent long exposure to wet and cold was responsible, though tight footwear was regarded as contributory, and infection, which occurred readily in the conditions experienced, might be added to complicate the lesion.

Relationship of the Lesions

Here, then, are three conditions—chilblain, erythrocyanosis of the leg, trench foot—separately described, but increasingly regarded as different manifestations of essentially the same process and as resulting from prolonged action of cold. They have a very great deal in common: in the early stages itching or tender, presenting coldness and high vascular coloration, they may proceed to swelling, blistering, and ulceration in all three instances. That necrosis belongs more to trench foot finds a natural explanation.

* The third, and last, of these lectures, on "Frost-bite," will appear in our next issue.

ation in the severity of damage and in a neglect enforced by conditions of service. Indolence of the lesions and slowness of healing are common to all three.

Their chief distinctions lie in their locations, and these are clearly fixed by manner of exposure. Chilblains come on exposed hands and on just those parts that cool most profoundly; when they affect the foot they will often display the areas of chief exposure, appearing in women on the dorsum and sharply defining the parts of the foot unshod. Erythrocyanosis is particularly a woman's malady, and as a frequent lesion is recent: its prevalence dates from the shortening of skirts and the use of thin stockings. In "trench foot" it is the foot only that has long been wet and cold.

A comparison of the microscopical lesions of chilblain and erythrocyanotic skin confirms the view of their close relationship. The lesions are those of subacute or chronic inflammation: widened vessels, oedema, and perivascular infiltration form the essence of the picture, until destructive lesions, also of common pattern, are added (Gans, 1925; Grattan, 1922, 1923; Hodara, 1906; Juster and Delàter, 1926; Pautrier and Ullmo, 1928). Haxthausen (1930) has rightly insisted on their general resemblances. Of the histology of trench foot we know little or nothing directly. But we do know that trench foot not infrequently presents macroscopically a picture identical with that of large chilblain (Grattan, 1922, 1923). It is a mistake to regard the lesions as we see them as specifically distinct: they present a common, fundamental, and hardly unexpected picture.

If it is accepted that chilblain, erythrocyanosis, and trench foot are in their origins essentially similar, further discussion may be concentrated upon one of these.

Pathogenesis of Chilblain

Our interest in the pathogenesis of chilblain cannot be satisfied by referring to H-substance release. Such release would of course account for the itch, the redness, and the swelling. Chilblain, however, is more than a simple vascular response; it is supplemented by other processes—namely, diapedesis of red and white cells, infiltration by various types of inflammatory cell, hyperplasia of epidermal and connective-tissue cells, etc. These are all phenomena common to subacute inflammatory processes occurring in response to diverse injuries, such as repeated friction or long-continued action of heat. They are the natural and inherent reactions of the skin to injury in general. The interest of the problem is no longer in the lesions themselves but in the manner in which injury arises, and inquiry may take one of several directions

In Chilblain Subjects, are the Immediate Reactions of the Skin to Cold Normal?

The reactions of a finger to crushed ice may be taken first. If the subject is sitting ordinarily clad in rooms at temperatures of from 19° to 21° C. (66° to 70° F.), it is the rule for the finger to react well, its temperature rising 4° to 8° C. (7° to 14° F.) within 10 to 20 minutes of its cooling. At lower room temperatures—namely, 17° to 19° C. (63° to 66° F.)—the reaction is usually smaller and delayed or fails. A chilblain subject sitting very warmly clad out of doors, the temperature being 6° C. (43° F.), showed a large reaction of the finger (8° C.) after cooling. Tenderness following such exposure to cold is no greater than that displayed by normals. Thus the normal mechanism of defence against injurious cooling is present in these cases. It is limited in them in one sense only. The reaction of the finger of normal subjects is neither so free nor so prompt if the forearm is unusually cold, because this coldness tends to close down the vessels of the forearm through which blood passes on to the region

that is called upon to react. The forearm of the chilblain subject is in general colder than that of the normal, and thus the defensive mechanism, though intact, is less effective.

The immediate reaction of the chilblain subject's skin to histamine pricked in, or to simple injuries of any kind, is normal, provided that the skin is naturally warm when so tested. The reactions of skin, whether belonging to the normal or the chilblain subject, are less intense but more prolonged if the skin is cold. Thus the chilblain subject's skin reacts normally when tested under standard conditions, but the coldness of the chilblain skin modifies the reaction.

If the hand of a chilblain subject is immersed in cold water (3° to 5° C.; 37° to 41° F.) for a period of two hours its appearance at the end does not differ from that of the similarly treated normal hand. There are the same signs, described in the first lecture, of vascular dilatation and oedema—signs that subside within a few hours. As stated in the same lecture, there are rare instances in which cold damages skin very unusually, producing acute whealing. These subjects are not prone to chilblain; neither do chilblain subjects present this phenomenon.

However the skin of the chilblain subject has been tested in its immediate reaction to injury it does not depart from the normal.

Production of Chilblain by Prolonged Cooling

In the chilblain subject it is very unusual for a finger that has a normal appearance to develop chilblain after immersion in ice-cold water for half an hour. In no instance out of many such tests have I seen such an after-effect. But I have known chilblain follow more prolonged cooling. Thus an exposure of the hands out of doors for two hours at 9° C. (48° F.) followed by an hour in a cold room and warming of the fingers before a stove produced in a predisposed subject the first chilblain of the season. A patient usually suffering from chilblains on both hands was asked to immerse the left or less susceptible hand for five minutes in cold water (5° to 10° C.) ten times a day. She continued to do so for a month, and then developed chilblains on several fingers of this hand, the right remaining without them. These observations bear out the statements of many patients and emphasize the importance of prolonged or repeated cooling. There is, however, a very real difficulty in arriving at true values for the duration of cooling required. A patient suffered regularly in the winter from chilblains; during the autumn, before any chilblain had appeared, her hand was immersed in water for a period of two hours at 7° (45° F.). The hand had resumed its usual appearance within two hours, but at five hours a typical chilblain had begun to form on the little finger; it blistered the same evening and healed in a few days. Now, it is to be observed that such an exposure does not cause chilblains in a normal subject and that all five fingers of the patient's hand were similarly exposed but one only developed chilblain. The reason may be found in the fact that the chilblain appeared on the dorsum of a proximal phalanx where seven months previously a chilblain had occurred, and which still presented a persistent reddening and a little thickening of the skin. The observations, at all events, definitely support the idea that an area that has suffered once is one specially prone to suffer again. Here attention may be drawn to the fact that skin which has previously been damaged is in general prone to react. Thus scars left in the skin from small infected wounds sometimes, and temporarily, become red and swollen, and itch, from time to time without obvious reason. A man who has had trench foot is stated to be more prone to have it a second time. But, recognizing that there is this proneness in the case of chilblain, it is impossible accurately to

determine by observation the amount of cooling needed to produce a lesion in a chilblain subject; for in no experiment can we be sure of the extent of preliminary damage that is present: the final or provocative cooling may be regarded as adding its quota of damage, the sum of which leads to an obvious reaction.

We are brought to ask if there is evidence that cooling can produce chronic inflammatory lesions in skin that has previously displayed no chilblain or predisposition, and, if so, how much cooling is required in these. Smith, Ritchie, and Dawson (1915-16) were prompted by observations upon trench foot, during the last war, to expose the shaved feet of rabbits to damp cold. The rabbits stood on cold or half-frozen mud. Swelling of the feet was visible in forty-eight hours, and subsequently increased; microscopically they found oedema, perivascular infiltration, and other evidences of vascular damage, including fibrin in the tissue spaces. They thus proved that, in the rabbit, simple prolonged exposure to cold can produce a subacute inflammation of the skin and subcutaneous tissues of the feet. And the time required was about two days. The data we possess indicate that "trench foot" usually requires longer exposure or repeated exposures.

It is noteworthy that patients displaying trench foot for the first time give no previous history of trouble with feet or of chilblains (Smith, Ritchie, and Dawson, 1915-16). Though susceptibility no doubt varies, the lesions may be regarded as occurring in normal people. Chilblains appear on the foot and leg of children paralysed by anterior poliomyelitis, but only when disuse has brought the limb to a state of almost persistent coldness for a long period; here intermittent exposure of weeks or months is responsible.

The Predisposing Cause of Chilblain

It has been suggested that chilblains are associated with an altered blood-coagulation time (Wright, 1897); but such change is not found with constancy. The only predisposing cause which can be cited because constant, in the case both of chilblain and of erythrocyanosis of the leg, is an almost habitually defective circulation in the limbs; so that the temperature of the skin often falls close to that of the surrounding air, in circumstances in which a normal limb circulation would preserve a natural warmth. The limbs are cold not only in cold but also in cool surroundings. There are many distinct conditions in which the blood supply to a limb is defective, and in all these chilblains often occur. Thus they are frequent in the limbs in syringomyelia, anterior poliomyelitis, and conditions of coldness from disuse; they are found in acrocyanosis, in Raynaud's malady, and in thrombo-angiitis, where blood-flow deficiency results variously in spasm of vessel wall or thrombotic obliteration of the vessels (Lewis and Pickering, 1936).

As the examples of trench foot, and of chilblain in anterior poliomyelitis, illustrate, there is reason to believe that adequate and sufficiently prolonged cooling will produce inflammatory states of the skin originally quite normal. It is to be expected that given exposures will produce chilblain more readily in subjects in whom the skin temperature falls most readily. It is to the high vascular tone of the limb vessels, to the readiness with which the temperature of fingers or other part falls to that of its surroundings, and to the long delay in the release of this spastic condition of the vessels after general vasodilatation sets in, that the chilblain subject seems to owe his predisposition to these lesions.

Smith, Ritchie, and Dawson found in their rabbits that strapping the legs intensified the injury due to exposure; it is recognized that tight footwear increases the frequency of

trench foot; and in a chilblain subject I have seen chilblains appear only on a strapped foot when both feet had been equally exposed to cold for some hours in a deliberate test. In all these instances the explanation lies in hindrance to blood supply causing greater cooling on exposure.

The indolence of chilblain and of erythrocyanosis, once such lesions are established, is also clearly explicable on this basis of deficient circulation; and nothing leads more quickly to recovery than the re-establishment of a flow of blood to the affected parts adequate to bring their temperature to and maintain it at normal levels. The essence of treatment lies in establishing natural warmth. The affected parts are to be directly protected from exposure to cold and from mechanical injury; and relaxation of the limb vessels is to be induced by warming the trunk with extra clothing, by warmer rooms, and, when necessary, by confinement to bed.

SOME EFFECTS OF VITAMINS B AND C ON SENILE PATIENTS

BY

W. STEPHENSON, Ph.D.

C. PENTON, B.M.

AND

V. KORENCHESKY, M.D.

(From the Littlemore Hospital, Oxford, and the Institute of Experimental Psychology, Oxford University)

The literature on the effects of vitamins B and C on the aged is not great.

Vitamin C in Old Age

Yavorsky, Almaden, and King (1934) investigated the amount of ascorbic acid in human organs at different ages. They found that with ageing the organs become poorer in this vitamin. For example, the following amounts of ascorbic acid in milligrammes per gramme of organs were recorded:

	Age: 1 to 30 days	11 to 45 years	46 to 77 years
Adrenals	0.551	0.393	0.230
Brain	0.460	—	0.110
Liver	0.149	0.135	0.064
Kidney	0.153	0.093	0.047
Lung	0.126	0.065	0.045
Heart	0.076	0.042	0.021

A similar decrease with ageing occurred in pancreas, spleen, and thymus. Marinesco, Alexianu-Buttu, and Olteanu (1936) estimated the amount of ascorbic acid in the cerebrospinal fluid (in mg. per 100 c.c.m. of fluid), and found in children up to 10 years old 2.8 to 2.2 mg., in persons aged 20 to 30 years 1.4 to 1.1 mg., in those aged 50 to 60 years 0.6 to 0.4 mg., and in those over 70 years old 0.3 to 0.2 mg. A low level of vitamin C in the blood, cerebrospinal fluid, or urine of aged people was also recorded by Plaut and Bülow (1935, 1936), Gander and Niederberger (1936), Altmann and Goldhammer (1937), Monauni (1937), Remp, Rosen, Ziegler, and Cameron (1940). The last-named authors, and also Plaut and Bülow, and Gander and Niederberger, were able to increase this low level by oral administration of ascorbic acid, which appears to exclude the possibility that this condition can be caused by decreased

absorption of the vitamin from the intestinal canal of senile persons. A probable cause of the low vitamin level would be deficiency of vitamin C in the diet of old people. For example, Yavorsky, Almaden, and King (1934), Malmberg and Euler (1935), and Wortis, Wortis, and Marsh (1938) observed a sharp decrease of vitamin C levels in adrenals, liver, brain, and kidneys of guinea-pigs fed on a diet deficient in vitamin C. Also, Schroeder (1939) found in human beings on a diet poor in vitamin C only 0.8 mg. of ascorbic acid per 1,000 c.cm. of blood instead of the usual 10 mg. on a normal diet. These experiments, however, were not on aged persons.

The clinical observations of Plaut and Bülow (1935) and Monauni (1937) indicate that the decreased amount of vitamin C in older persons cannot be explained merely by the low content of this vitamin in the diet, because the difference between young and old persons is present even when both groups are receiving the same hospital diet. Plaut and Bülow, and Wortis *et al.*, have therefore suggested that in senile persons there is a decrease in intensity of those metabolic processes in which vitamin C is taking part. In our opinion the administration of extra-large quantities of ascorbic acid very probably compensates this faulty metabolism or deficient absorption, and this explains the increased content of ascorbic acid in the urine of senile patients receiving large amounts of the acid.

Berkenau (1940) found definite hypovitaminosis-C in senile psychoses, and Bersot (1936) in some mental and nervous diseases. Wortis, Wortis, and Marsh recorded a subnormal vitamin C content of the blood and cerebrospinal fluid in alcoholic patients who suffered also from neuritis or psychopathy. They therefore suggest that a nutritional factor may play a part in the production of mental and nervous diseases. Gander and Niederberger found that treatment of senile persons with adequate doses of ascorbic acid was followed in some cases by improvement of the general health, increased vitality, better sleep, disappearance of rheumatic pains, and a favourable effect on pneumonia of senile patients. Schroeder, reviewing the literature of the subject and the results of his own observations, considers 50 mg. of ascorbic acid to be the minimum daily dose for human beings.

Vitamin B Complex in Old Age

Greying of Hair.—Niemes and Wacker (1922), Hartwell (1923), Bakke, Aschehoug, and Zbinden (1930), and Gorter (1934, 1935) recorded greying, bleaching, or yellowing of hair in rats with dark fur on different deficient diets. Gorter claimed that an insufficient amount of copper salts was responsible in his experiments for the depigmentation of the fur, which he was able to prevent or to cure by the administration of copper salts. Since György (1935) was not able to cure the bleaching of the fur of rats on a vitamin-B-deficient diet by supplementing the diet with aneurin, lactoflavin, and Peters's eluate factor, none of these factors could be considered as the anti-greying compound. Morgan, Cook, and Davison (1938), Morgan and Simms (1939, 1940), Morgan (1941), Lunde and Kringstad (1939), and Mohammad, Emerson, Emerson, and Evans (1939) have confirmed that greying of hair develops regularly on vitamin-B-deficient diet, and, in addition, have proved that of all the B complex the "filtrate factor" alone can prevent or cure this pathological condition. At the same time, the experimental results of these authors suggest that very probably the filtrate factor contains two vitamins, one anti-greying proper and the other growth-promoting. Oleson, Elvehjem, and Hart (1939) also came to the conclusion that the anti-greying vitamin is different from all the known B factors.

Morgan and co-workers produced greying of the fur, and cured it with the anti-greying vitamin, in dogs and silver foxes as well as rats. It still remains to prove, however, that in natural ageing deficiency of this vitamin is at least partly responsible for the greying of hair in old age, and not some other cause. For instance, Morgan and Simms (1940) themselves recorded that injections of cortin and thyroid extract can cure, although slowly, the greying of hair in deficient rats. In his latest paper Morgan (1941) stresses the fact that rats on a diet deficient in the filtrate factor show, in addition to greying of the fur, some other signs of ageing—loose wrinkled skin, sparse hair, atrophic adrenals, and finally emaciation with ulceration of the skin.

Presence of Some Similar Pathological Changes in Vitamin B₁ or Nicotinic Acid Deficiency and in Senility

Williams, Mason, Wilder, and Smith (1940) produced experimental deficiency in 6 normal healthy women for a period of 88 days on a diet sufficient in all vitamins except aneurin (B₃). Among the symptoms observed by these authors the following features also often occur in senile patients: depressed mental state, weakness, dizziness, easy fatigability, backaches, soreness and atony of muscles, palpitation, dyspnoea on exertion, reduction of the capacity for physical and mental activity, difficulty of concentration and memory, insomnia, headaches, abdominal distension, and roughness of the skin. McLester (1939) and Spies, Hightower, and Hubbard (1940) give an account of "pre-pellagrous prodromal" forms of nicotinic acid deficiency. In the symptoms described it is also possible to note some features usually occurring in aged people: rashes, symmetrically and bilaterally developing on the skin; mental disturbances such as apprehension, confusion, disorientation, nervousness and forgetfulness, depression, weariness; and also increased fatigability, headaches, and insomnia. While pointing out the similarity of the features, however, we should like to note that the same pathological conditions might be produced by altogether different causes, and therefore the similarity might suggest only the desirability of investigating the possible significance of B vitamins in the process of senescence.

Some encouragement is afforded by the results obtained by Cleave, Sydenstricker, and Geeslin (1939), who treated 19 patients with nicotinic acid. Of these, 12 were old, with advanced arteriosclerosis, presenting a clinical picture commonly attributed to arteriosclerotic encephalopathy; 5 showed marked deafness. All of them were suffering from hebeticism amounting to profound stupor, which was a most prominent feature of the disease. Improvement obtained after the treatment was so remarkable that the authors conclude that "nicotinic acid was life-saving in all but one or two of the cases under discussion." The deafness was also much relieved, especially in two cases.

Another reason for investigating the effects of vitamins B complex and C on senile persons is based on the admission, accepted by most specialists in nutrition, that at the present time a partial deficiency of vitamins B and C is more widely prevalent among the populations of Europe and America than was previously thought. Corroboration of this, for example, is given by the deficiency of vitamin C, referred to above, in the blood, cerebrospinal fluid, organs, and urine of aged people.

Present Investigation

The total number of patients concerned in the clinical trial at the Littlemore Hospital was 58 (one patient left the hospital after Period III). The effects of vitamins B and C were studied on 40 patients (15 males and 25 females), while the remaining 18 (males) formed a control group receiving dummy pellets of lactic sugar. The investigation was of about a year's duration.

Vitamin B complex was given in the form of dried yeast specially prepared in the Government's Chemical Research Laboratory at Teddington, to the Director of which, Dr. G. S. Whitby, and to Dr. A. C. Thaysen, who was responsible for its preparation, we express our gratitude. The single dose was about 25 grammes, given as a sweetened suspension in water three times a week. The yeast was supplemented by tablets of pure crystalline vitamins, given three times a week in the following single doses: 5 or 3.3 mg. aneurin (B₁), 5 or 3.3 mg. lactoflavin, and 50 or 33.3 mg. nicotinic acid. We are most grateful to Prof. R. A. Peters, who suggested these doses. Vitamin C was given as pure ascorbic acid three times a week, each dose 200 or 300 mg. All crystalline vitamins B and C were supplied in generous amount by Messrs. Roche Products Ltd., to whom, and in particular to Dr. F. Bergel, we offer our thanks.

Observations on the 40-patients of the experimental groups were divided into five periods, each of 8 or 9 weeks' duration, during which examinations and tests were

repeatedly performed. These treatment periods alternated with rest periods of 10 to 14 days:

Period I ("Pre-treatment period").—All patients.

Period II.—During this period vitamin B complex preparations were given to 20 patients (first group, 7 males and 13 females), and vitamin C to the remaining 20 (second group, 8 males and 12 females).

Period III.—The first group was now given vitamin C, and the second group vitamin B complex. Thus each of the 40 patients was receiving either vitamin B ("Vit. B Groups") or C ("Vit. C Groups") treatment. In the tables (p. 842) the results obtained from groups similarly treated have been pooled.

Period IV.—To all the patients of the experimental groups both vitamins B and C were given simultaneously ("Vits. B + C Group") in the doses described above.

Period V.—"Post-treatment period" of 4 to 5 months, during which no treatment was given.

In the clinical investigation special attention was paid to changes in senile features (see later). In addition, blood examinations were made on the number of red cells and haemoglobin content. The urine was examined for albumin, casts, and sugar.

Dr. Stephenson applied psychological tests of psychomotor speed (tapping on three keys arranged in triangle fashion) and of psychomotor co-ordination (tapping with two hands co-ordinately on three keys). Besides this he tested (a) muscular power by dynamometer grip for each hand alternately, using the apparatus of Cheron and Verdin; (b) compression power for left arm; and (c) extension power for right arm, using apparatus devised and constructed by him, which will be described in detail elsewhere, together with the results of some additional psychological tests used (reaction to visual stimulus, card-sorting, and manual dexterity).

For economy of space we have tabulated only some of the clinical, psychological, and ergographic results, presenting them in the briefest possible way. Senile features not included in the tables will be discussed in the text.

Age and Condition of Patients

The average age of the patients in the treated group was 73, varying from 65 to 86; in the control group 71½, varying from 60 to 87. So far as was possible the patients were distributed evenly in the different groups according to their age and the severity of the senile changes, although these changes were on the average slightly fewer and less severe in the control group.

All the patients were suffering from dementia senilis, which, however, varied greatly in degree; in some cases the dementia was secondary to a previous psychosis. Delusions complicated 13 cases and hallucinations 5 cases. Besides dementia senilis, some or all of the following usual features of senility or those that accompany ageing were present, and their changes were recorded during repeated examinations: increased bony prominences of the face, sunken eyes and cheeks, stooping, general weakness, flabby muscles, uncertain movements, tremors, stiffness of joints and of stretching and bending movements, shuffling gait, rheumatism, flabby shrunken genitalia, obliterated interosseous spaces, parchment skin, wrinkles, rashes, senile itchings, discoloration and pigmentation of skin, senile hair, dry mouth, fissured coated tongue, impaired digestion, constipation, flatulence, husky cracked voice, uncertain slow speech, shortness of breath, dim vision, arcus senilis, red conjunctivae, deafness, arteriosclerosis, varicose veins, haemorrhoids, oedematous eye sacs and ankles, weakened or lost control of bladder and bowel action, dullness of sensory nerve endings, easy chilling, daytime sleeping, and nocturnal insomnia. The number of patients showing some of these senile features is given in Tables I and II, column 2.

Those features in which no numerous or pronounced changes were noted have not been tabulated, but will be mentioned in the text.

Excretion of Vitamin B₁ in Urine

The patients received the usual hospital diet, sufficient in calories but restricted in greens (three times a week), fruit, or fresh lettuce (once a week, if available). The vitamin content of the diet was limited. The amount of vitamin C in the organs and urine of aged people has already been repeatedly investigated by other workers, so it was decided to assay the amount of vitamin B₁ in the urine. Every effort was made to collect the whole of the twenty-four hours' urine and to mix it with preservatives (HCl and toluol) as quickly as possible after excretion. This was not easy to arrange with demented senile patients. Therefore, although the qualitative changes obtained in the different groups were clearly defined, the actual figures should be considered with some reservation. The assay of vitamin B₁ in the urine was performed by Dr. H. W. Kinnersley in Prof. R. A. Peters's Department of Biochemistry at Oxford University. We are most grateful both to Dr. Kinnersley and to Prof. Peters for their kind help.

In the urine of the control senile patients not treated with vitamins (16 patients were examined) an average of about 5 γ of vitamin B₁ was excreted during twenty-four hours; in the urine of those treated with vitamin C (9 patients) about 6 γ, and in that of those treated with vitamin B complex (8 patients) 156 γ. The average excretion of vitamin B₁ in the urine of 25 young soldiers suffering from different mental diseases, in the same hospital, was about 34 γ, but their diet contained a little more of cooked and fresh vegetables. Therefore, without further investigations it is impossible to decide whether the very low figures of B₁ excreted in the urine of senile persons were due only, as is the case with vitamin C, to some disturbance in senile metabolism in which vitamin B₁ is involved, or not. The average amount of urine excreted and collected in twenty-four hours was 1,335 c.cm. in control senile persons, 1,006 c.cm. in senile patients treated with vitamin C, 1,556 c.cm. in patients treated with vitamin B complex, and 1,667 c.cm. in the control young patients.

Body Weight and Fat Deposition.—Towards the end of the experiment there was a slight loss of body weight in both the control and treated groups, but no pronounced changes were observable in the subcutaneous fat of the patients.

Mental Condition

1. *Clinical Observations*.—In most cases the changes in mental condition were not great, but were quite definite. Where, for instance, "improvement" is recorded it consisted in a marked improvement or sometimes even in the disappearance of two or more, or all, of the following abnormalities: the patients became less incoherent and more intelligent in their talk, less depressed or less excited, less restless with fewer aimless movements, brighter and more friendly and sociable and less quarrelsome, and cleaner in their habits; they started to recognize relatives and nurses, performed better work; and nocturnal insomnia and day sleeping improved or disappeared. The percentage of improved cases was much greater and that of deteriorated cases considerably less in the treated (Table I) than in the control groups (Table II), and the number of improved cases grew steadily during the three successive periods of the treatment. After the treatment, although the change for the better was maintained in most of the improved cases, the number of deteriorated cases increased, including some of those which improved during the treatment. The improvement in a few of the treated cases was really remarkable. For example, in one case the patient before

the treatment had no control over her bladder and bowel, was dirty in her habits, very depressed and stuporous, showed no intelligence in her behaviour and talk, and did not recognize her relatives or the nursing staff. At the end of the treatment all these abnormalities had disappeared, except for occasional slight confusion in thought.

In the control group delusions were present in 6 patients and hallucinations in 2, and no improvement was recorded in any; in the treated group, in 5 out of 13 cases of delusion a pronounced improvement (in one case disappearance) was noted, and in 1 out of 5 cases there was a disappearance of hallucinations. It should be mentioned, however, that in the "post-treatment period" delusions returned in 4 patients—i.e., in the majority of cases the improvement lasted only during the period of treatment with vitamins. Nocturnal insomnia definitely improved or disappeared in a considerable number of cases (compare Tables I and II), while day sleeping was recorded less frequently in those who were subject to it.

2. *Psychological Effects* (W. Stephenson).—The objective results of the psychological tests (Table III, Tests 1 and 2)

again corroborated the clinical observations and recorded a definite improvement in the mental condition of the treated group. The results of the psychomotor co-ordination test are perhaps particularly demonstrative, showing as they do some improvement, in a lesser degree, even in the post-treatment period.

TABLE III.—*Averaged Effects of Vitamin Treatment as shown by Psychological Tests and those of Muscular Power, compared with the Same Tests (performed at Approximately Two-months Intervals) on Control Senile Persons*

Tests	Periods of Observation on Controls :				
	I	II	III	IV	V
	Periods of Observation on Treated Group :				
	Pre-treatment	Vit. B	Vit. C	Vits. B + C	Post-treatment
1. Psychomotor speed :					
Control	100	100	101	105	99
Treated	100	109	113	110	101
2. Psychomotor co-ordination :					
Control	100	102	102	106	102
Treated	100	114	121	119	116
3. Dynamometer grip :					
Control	100	99	105	99	105
Treated	100	110	112	110	103
4. Averaged compression (left arm) and extension (right arm) power :					
Control	100	101	100	99	109
Treated	100	128	122	147	130

Note: The quantitative changes of the tests are expressed as percentages of initial score (taken as 100) of Period I in control senile persons; or, in the treated senile patients, as percentages of the pre-treatment period (also taken as 100).

Muscular System

1. *Clinical Observations*.—Muscular function definitely improved under the treatment (Table I) as judged by the favourable effects on stooping, shuffling gait, uncertain movements, tremor in the hands, and stiff movements. At the end of the "Vits. B + C period" of the treatment improvement was such in the patients with mild or medium changes that these senile features completely disappeared or were present only in very slight degree—in the case of stooping in about one-quarter, uncertain movement in about three-quarters, shuffling gait, tremors, and stiffness of movement in about a half of all the "improved" cases shown in Table I. Hirata and Suzuki (1935) observed hypovitaminosis-C in patients suffering from progressive muscular atrophy. Treatment with vitamin C improved their condition considerably.

2. *Tests with Dynamometer and Ergographs* (W. Stephenson).—These tests corroborated the clinical observations and are particularly useful because their results can be

presented quantitatively. As the data for Tests 3 and 4 show (Table III), a distinct improvement was obtained during the treatment with vitamins B and C (the larger differences between the treated and control groups are statistically significant, as will be shown in a later, more detailed, paper on these tests). Ergographic results on arms (Test 4) were much more demonstrative than those with the dynamometer (hand grip, Test 3): this is most probably due to the greater sensitivity, greater reliability, and more comprehensive nature of the ergographic tests as compared with the less reliable and cruder dynamometer.

Cardiovascular System

There is a convincing amount of literature demonstrating a causative association between cardiovascular disturbances and partial deficiency of vitamin B₁. These symptoms are promptly cured by vitamin B₁ administration. The extreme form—"cardiac beriberi"—is very dangerous, but even the milder forms call for the closest medical attention. A good summary of the literature on the subject, with an account of their own cases, is given by Weiss and Wilkins (1936) and Weiss (1940). Weiss and Wilkins described these mild forms as various combinations of tachycardia, or vagus reflex irritability with bradycardia, sometimes with astyole and syncope, one-sided heart failure, peripheral arteriolar dilatation or vascular constriction, or vasomotor collapse. Histological changes were found to be similar to those described in "beriberi heart."

In our patients we have not noticed well-defined symptoms as described above. In two, however, *extrasystoles* which had been present for a long time before the treatment disappeared after the administration of vitamin B complex.

No constant or significant changes were observed in the "resting" blood pressure and pulse rate. Although varying in individual cases, the average figures obtained in all of the 40 patients were remarkably close. For example, the average systolic-diastolic pressure before the treatment was 170/95; at the end of each of the three succeeding periods of treatment the values were 169/86, 169/91, and 167/89 respectively. In the control group the average figures at the beginning and end of the observations were 165/89 and 154/82 respectively. No change was noticed in the degree of *arteriosclerosis* of the treated patients. Some definite improvement was indirectly recorded, however, in the function of the cardiovascular system, because the *shortness of breath* and *oedematous eye sacs and ankles* completely disappeared or were much improved in a large percentage of the cases, as shown by a comparison of the data in Tables I and II. No changes were noted in the condition of the *varicose veins* or *haemorrhoids* of our patients, in none of whom were these conditions severe. Krieg (1938) and Ochsner and Smith (1940) were able to decrease pain in the varicose veins and ulcers considerably, and Krieg even noticed a contraction of the varicose veins after administration of vitamin B₁. This latter, however, was not confirmed by Ochsner and Smith.

Skin and Hair

Dullness of the nerve endings in the skin was recorded in 28 of the treated patients; it improved in 9 cases, appeared in one new patient not previously suffering from it, and persisted unchanged in the remaining patients towards the end of "B + C period." In the control group no improvement was noticed in any of the patients; it persisted in 12 who had had it from the beginning, and newly appeared in 2 others. Complexion, wrinkles, and parchment-like skin were also unchanged, but the senile patchy pigmentation of the hands appeared to be less pronounced in most patients at the end of the third period of

the treatment. Quite definite improvement or in some cases complete disappearance of senile skin itchings and rashes was recorded (Table I) in a considerable percentage of the treated cases, the highest figures being obtained when vitamins B and C were administered simultaneously. In the control group (Table II, Examination III) no such improvement was recorded.

In the literature some favourable results were recorded with vitamin B in skin diseases; for instance, pellagra rashes could be quickly improved by the administration of nicotinic acid and aneurin (Boyd Campbell and Allison, 1940). A good result was obtained by Kristensen and Vendel (1940) in the treatment of chronic eczemas with yeast extract, and by Madden (1940) in the case of psoriasis treated with aneurin.

No changes were noticed in the grey hair, growth of bristles, or baldness in the treated senile patients. The scarcity or absence of hair in the axilla was also uninfluenced.

Digestive Tract

The tongue was fissured or coated, or both, in 22 cases; by the end of the third period of treatment it became better or normal in about half of them, while dry mouth disappeared in only a few. Constipation was a symptom which improved or disappeared in most of the treated patients (Table I) but in none of the controls (Table II). The treatment had no effect on flatulence. No other serious disorders in gastro-intestinal function were noted. Satisfactory results in the treatment of cases of constipation with aneurin have repeatedly been published, and a good review of the literature on the subject has been given by Harris (1938). Gastro-intestinal distension and atonia have been found to be prominent features of aneurin deficiency both in men and in animals (Harris, 1938).

Other Senile Features Examined

Easy chilling improved or disappeared after combined treatment with vitamins B and C in about half of those cases in which this feature was present before the treatment (Table I); the body temperature did not on the average show any definite changes in all the five periods examined. Husky cracked voice, present in different degree in almost all the treated and control patients, became clearer in only 2 of the treated cases.

Uncertain slow speech persisted in 3 patients and appeared in 3 more of the control group at the end of the period of observation. In the treated group it was present before treatment in 11 patients, in 5 of whom it definitely improved or disappeared; but 2, not affected in this way before the treatment, had begun to suffer from it by the end of the third period.

Rheumatism, atrophied interosseous spaces, deafness, dim vision, arcus senilis, and red conjunctivae were not definitely changed in either the treated or the control group.

Red Blood Cells and Haemoglobin

Although varying in individual cases, there was on the average in the treated group a hardly significant increase of the red cells and haemoglobin during the treatment. (The respective figures were: before treatment—red cells 4,850,000, Hb 89; vitamin B groups, 5,090,000 and 92; vitamin C groups, 5,160,000 and 99; vitamin B + C groups, 5,110,000 and 93.) In the control group the decrease of red cells from 5,080,000 to 4,930,000 and of Hb from 93 to 89 was also insignificant.

Post-treatment Period

If the data of the "post-treatment period" (Table I) are compared with those of the previous periods in the experimental group and with those of the last examination

in the control group (Table II), it becomes clear that certain typical changes occurred after the end of the treatment. Thus about four months after the treatment finished considerable deterioration had occurred, consisting in particular of disappearance of the improvement obtained during the treatment, and also of the appearance of some new cases of deterioration. This indicates that in some cases improvement of certain senile features and prevention of further senile deterioration can be maintained only if treatment with the vitamins is continued. In spite of this relapse in a number of cases, however, in numerous others the improvement obtained by the vitamin treatment was maintained after its discontinuation. This was demonstrated by the clinical observations (Table I), the psychological test (Table III, Test No. 2), and the ergographic test (Table III, Test No. 4).

Experiments on deficient animals have shown that the specific effects of vitamins B and C do not last long after the end of the administration of these vitamins. Therefore it is most probable that the explanation of the lasting action of the vitamins in some of the senile patients lies in the disruption of those secondary vicious circles which are originated by pathological changes in different organs (e.g., sex glands, adrenals, gastro-intestinal canal, liver, etc.), changes in these organs in their turn being produced by the direct action of vitamin deficiency. These secondary pathological conditions, being specific for dysfunction of the affected organs, become additional to those caused by pure vitamin deficiency proper. Of course, when the effects of the discontinued vitamin treatment have worn off, the repair of the organ concerned disappears after some time and the secondary vicious circles return.

Summary

Forty senile patients were treated with vitamins B complex and C, the whole period of observation lasting for about a year. The condition of these patients was compared with that of 18 senile patients of a control group receiving dummy tablets. All patients were on a usual hospital diet not rich in vitamins.

Treatment with vitamins B and C, as with any other remedy, did not stop the biologically inevitable development of senility, and therefore did not affect those basic features which are specific for and present in even the most physiological type of senility.

By treating the aged people with vitamins, however, it was possible to prevent or improve, in some cases to a striking degree, certain of those senile features which could be considered as pathological, because they appear prematurely or in an extreme degree (e.g., muscular, cardiovascular, and mental deterioration) or which do not seem to be inevitable in normal physiological senility (e.g., dementia, insomnia, skin rashes and itchings, constipation).

During the period of observation improvement or disappearance (apparently not of a lasting nature) of some pathological senile features was observed in numerous cases, while a number of other cases were not improved by the treatment, and a few patients who had been free from certain senile features developed them during and notwithstanding the treatment.

In spite of the comparatively limited and modest results which aged people might expect from treatment with vitamins, it seems clear that in suitable cases the relief obtained in some pathological senile features might be considerable.

The results obtained provide strong support to the argument, repeatedly emphasized by several specialists in the modern science of nutrition, that the greatest care should be taken to prevent the occurrence of partial or latent vitamin deficiency, apparently widely spread in the population. This will result not only in the prevention of certain vitamin-deficiency diseases but probably also, in the approach to a less pathological senility.

We are most grateful to Dr. R. W. Armstrong, medical superintendent of the Littlemore Hospital, for all the help and facilities given during this research, and to Messrs. Arthur Guinness, Son and Co., in particular to Mr. Case, for a small

grant to cover the expenses. We also express our gratitude to Prof. F. R. Fraser for his interest in the research and criticism of its scheme and of the paper. Dr. Korenchevsky is indebted to the Medical Research Council and the Lister Institute for personal grants.

THE VALUE OF BLOOD TRANSFUSION IN MALIGNANT DIPHTHERIA

BY

IDWAL PUGH, M.B., Ch.B., D.P.H.

Deputy Medical Officer of Health, Swansea

AND

O. S. WILLIAMS, M.R.C.S., L.R.C.P.

Lieutenant, R.A.M.C.; late Resident Medical Officer, Hill House Isolation Hospital, Swansea

Judging by the lack of any published reports in English medical literature on the value of blood transfusion in malignant diphtheria, it would seem that this method of therapy has received little or no attention in this country. On the other hand, a review of the available literature goes to show that the subject has engaged the attention of certain Continental workers for some time.

Baar and Benedict (1933) treated 43 cases of malignant diphtheria with either "human serum" or blood transfusion. All the cases selected for treatment by transfusion were rigorously classified, nor were desperate cases with cardiac insufficiency discarded. Twenty-seven of the 43 cases recovered, giving a case mortality of 37.2%. The authors claimed that transfusion reduced the mortality rate of malignant diphtheria by one-half.

Moeller (1934) tried the method of giving blood in the proportion of 1/70 of the patient's weight. In all he transfused 19 cases: 5 were transfused late in the illness (6th, 7th, or 8th day), and of these four died; 2 were moribund on admission and died; of the remaining 12 cases, 7 survived. Moeller calculated the mortality rate at 41% in the transfused cases and at 66% in the non-transfused, but intimated that the number of cases was too small for any firm conclusions.

Darrow and Yannet (1935) emphasized the value of blood transfusion in malignant cases as a method of combating the

early toxæmic manifestations which in many respects were analogous to those of shock, and also in the maintenance of nutrition in those cases in which persistent vomiting precluded oral feeding.

The present investigation into the value of blood transfusion in malignant diphtheria was carried out during the 1940 epidemic of diphtheria in Swansea, which was characterized by the prevalence of malignant cases. The report is based on 40 malignant cases admitted to hospital between July, 1940, and January, 1941, of which 20 consecutive cases, admitted during the three months November, 1940, to January, 1941, were transfused.

Clinical and Therapeutic Considerations

It seems hardly necessary to recall here the clinical features of malignant diphtheria, since these are admirably described in modern textbooks on infectious diseases. We would mention briefly that the term "malignant" is applied to an unusually toxic form of diphtheria. The patient is as a rule apathetic and drowsy, and takes little interest in his surroundings. Locally there is extensive membrane, involving the tonsils, pillars, palate, and uvula, and extending on to the nasal mucosa, together with faucial and palatal oedema and redness, the oedema at times being so pronounced as to mask the real extent of the membrane. A profuse purulent or sanious nasal discharge is common and results in nasal obstruction and oral breathing. Swelling of the cervical glands and periglandular tissues is considerable. Fœtor is marked. Haemorrhage into the skin and from mucous surfaces is not uncommon. As a rule such cases show a slow response to specific treatment with antitoxin. The mortality is often as high as 50%, and those patients that recover usually suffer severe paralysis.

Up to November, 1940, malignant cases were treated at this hospital upon the following lines:

1. Prompt administration of a large dose of concentrated antitoxin, intravenously if possible, and partly intramuscular.
2. Intravenous infusion of 10% glucose in saline.
3. Absolute rest in the flat position with the foot of the bed raised.
4. Glucose drinks by mouth, except in those cases in which vomiting was troublesome and persistent, when oral feeding was stopped and salines with 5% glucose administered rectally.
5. Strychnine daily.

In spite of intensive antitoxic therapy it was felt that its value in malignant cases was limited, and in November, 1940, it was decided to investigate the possibilities of blood transfusion. The first case transfused responded so well that it was decided to continue with the investigation, and during the ensuing three months until the subsidence of the epidemic towards the middle of January, 1941, in all 20 consecutive malignant cases were transfused. Apart from the substitution of blood transfusion for the intravenous administration of glucose and saline, the treatment of the 20 transfused cases was strictly comparable in all other respects to that given to malignant cases admitted before November, 1940.

Transfusion Technique

Transfusion was performed as soon as possible after the admission of the patient to hospital, and in each case the total volume of blood given was approximately one pint. Stored citrated blood was used throughout, and whereas 14 of the cases were grouped beforehand and received blood of the same grouping, this preliminary was omitted in the case of 6 desperately ill patients who were transfused with Group O blood. The apparatus used for giving the blood was the Medical Research Council's blood transfusion outfit, and owing to the collapsed nature of the veins it was found necessary in each case to cut down on the vein. The blood was given cold, and in order to avoid over-

loading an already embarrassed myocardium the rate of flow was slow, the average duration of transfusion in the 20 cases being two hours.

Plan of Investigation

The object of this paper is to compare the results obtained in respect of 20 transfused cases (test series) with a similar number of consecutive cases of malignant diphtheria treated by the orthodox method outlined above, and which were admitted during the four months July to October, 1940 (control series). It is proposed to compare the results in the two series of cases with regard to the following criteria: mortality rate, immediate response to treatment, incidence and severity of complications, and total duration of stay in hospital.

Since the validity of such a comparison might easily be influenced by such factors as (1) the real extent of malignancy in individual cases and the amount of antitoxin administered, (2) the age and sex distribution of the patients, and (3) the duration of the disease before admission to hospital, these must first be briefly considered.

All the cases were under the direct supervision of one of us (I. P.) throughout, and they all received the same nursing attention. All were rigorously classified on admission, and their malignancy may be gauged from the fact that the total amount of antitoxin given in the test series and control series averaged 110,000 and 112,000 units per case respectively. In no single case was the total dosage of antitoxin under 100,000 units. That the two series were fairly comparable regarding age and sex distribution can be seen from Table I. Table II gives the day of disease on admission, and it will be noted that whereas all the cases in the control series were admitted on the second and third days, 5 in the test series were admitted later than the third day of illness.

TABLE I.—Age and Sex Distribution

Age	Test Series		Control Series	
	Males	Females	Males	Females
3-4 years	1	1	1	1
4-5 "	1	1	1	2
5-10 "	4	9	6	1
10-15 "	2	2	2	5
15-20 "		1		1
Total	7	13	10	10

TABLE II

	Day of Disease on Admission				
	1st	2nd	3rd	4th	5th
Test cases		6	9	4	1
Control cases		10	10		

Results

Mortality Rate.—Out of the 20 cases treated by blood transfusion in the test series there were 2 deaths, giving a case mortality of 10%, whereas in the control series there were 7 deaths and a case mortality of 35%. Of the 2 patients who died in the test series, one was moribund on admission and died the same day, a few hours after transfusion. The second died during the sixth week of the illness. At this time the patient was suffering from pharyngeal paralysis, and death occurred from cardiac failure as the result of an unfortunate attempt to institute nasal feeding. In the control series 5 patients died of profound toxæmia during the first week, while the other two fatalities were due to cardiac failure during the second week. Table III gives the number of deaths at different age periods.

TABLE III

Age	Test Series		Control Series	
	Cases	Deaths	Cases	Deaths
3-4 years	1		2	
4-5	1		3	2
5-10	13	2	7	3
10-15	4		1	
15-20	1			
Total	20	2	20	7

Immediate Response to Treatment.—A noticeable feature of the test series was the rapidity with which most of the cases responded to treatment as compared with the control series. It was noted in most of the transfused cases that during the days immediately following the giving of the blood the patient's apathetic and drowsy aspect was transformed into a bright and keen appearance, and the nasal discharge, the periadenitis, and the membrane rapidly cleared up, whereas such a rapid clinical improvement was not so prominent in the control series.

Complications.—As regards the incidence, and severity of complications in the recovered cases, the test series followed a more favourable course: of the 18 cases that recovered 4 were uncomplicated; the other 14 developed a total of 33 complications. In the control series all 13 recovered cases developed complications, with a total of 44 complications. Although complications of a mild character were common to both series, the more severe types, including cardiac irregularities, pharyngeal paralysis, and severe peripheral neuritis, were more prominent in the control series (Table IV).

TABLE IV.—Complications in Recovered Cases

	Test Series No.	Control Series No.
Recovered cases	18	13
Uncomplicated recovery	4	0
Complicated recovery	14	13
Complications :		
Mild { Precocious palatal paresis	8	1
Palatal paresis	1	5
Paralysis of accommodation	1	
Facial paresis	2	1
Squint	2	2
Absent or sluggish reflexes	8	10
Pharyngeal paralysis	3	7
Severe { Weakness and wasting of limbs	1	2
.. ..	1	3
.. ..	1	4
.. ..	6	9
Secondary cervical adenitis	1	
Otitis media	2	
Total complications	33	44

The incidence of paralysis in both test and control series is approximately equal, being 55% and 60% respectively. When, however, the severer forms of paralysis are considered alone it is found that they predominate in the control series, their incidence in this group being 35% as compared with 15% in the test series.

Duration of Stay in Hospital.—Table V gives the duration of stay in hospital of the recovered cases. Transfused cases made a more rapid recovery, the average duration of stay being 10 weeks as compared with an average duration of 13 weeks in the control series.

TABLE V.—Length of Stay of Recovered Cases

Weeks :	8	9	10	11	12	13	14	15	16
Test cases	6	3	3	2	1	3			
Control cases		2	3		1			1	6

Reactions following Transfusions.—Among the 20 cases transfused 3 developed a mild febrile reaction with a rise of temperature up to 100° F. soon after the giving of blood. In only one case was a definite rigor encountered.

Comments

In the 40 cases of malignant diphtheria under review it appears that following the introduction of blood transfusion, on the whole, the immediate clinical response of the patients to specific therapy was accelerated. Not only was the case mortality reduced from 35% to 10%, but there was a decided decrease in the incidence of the severer forms of paralysis, and the duration of stay in hospital of recovered cases was appreciably reduced. Admittedly the number of cases transfused is small, and we fully realize that in such circumstances the results are open to serious criticism. Nevertheless, we maintain that the results are sufficiently encouraging to warrant further investigation into the possibilities of blood transfusion in the treatment of malignant diphtheria.

Summary

The available literature on the use of blood transfusion in malignant diphtheria is reviewed.

The main clinical features of malignant cases are outlined.

The present investigation deals with a series of 40 consecutive cases of malignant diphtheria. The first 20 were treated in the usual orthodox manner; in the others treatment was supplemented with blood transfusion.

The transfusion technique adopted is described with special reference to the form of apparatus used, and the type, volume, and rate of administration of the blood.

The results obtained in the two series are compared, and it is suggested that the results for the transfused series are sufficiently encouraging to merit further investigation into the value of blood transfusion as a therapeutic measure in malignant diphtheria.

We desire to thank Dr. H. R. Tighe, medical officer of health, Swansea, for permission to publish this report. Our thanks are also due to Dr. A. P. Sladden, director of the Beck Laboratory, Swansea General Hospital, for his encouragement, help, and advice throughout this investigation, and to Dr. Joan Drury, assistant pathologist, Swansea General Hospital, whose friendly co-operation made this work possible.

J. S. Simmons (*South. med. J.*, 1941, 34, 62) states that early in 1940 the Surgeon-General requested that the chairman of the Division of Medical Science of the National Research Council should appoint committees composed of civilian leaders in the various medical specialties to advise the U.S. Army concerning its emergency problems. Another important health measure was instituted in February, 1940, when the Public Health Service was authorized to co-operate with the Army by improving sanitation and disease control in civilian areas adjacent to military stations and concentrations. The Surgeon-General has also obtained the assistance of the American Medical Association in classifying the medical personnel of the country and determining the availability of physicians for service in civil life and in the Army. The paper contains brief notes of the procedure applicable to (1) immunization of all military personnel against small-pox, typhoid and paratyphoid, and tetanus; (2) immunization against localized outbreaks of endemic disease such as scarlet fever; (3) immunization against uncommon and dangerous diseases to which the troops might be exposed at home and abroad—such as yellow fever, cholera, plague, and typhus.

SACRO-ILIAC STRAIN

BY

JAMES CYRIAX, M.D.

*Assistant Medical Officer, Physiotherapeutic Department,
St. Thomas's Hospital*

The uncertainty that surrounds the vexed question of sacro-iliac strain has provided a basis for much quackery. While some authorities doubt its very existence, others hold it to be a common cause of backache and of pains felt radiating down the lower limb. Bone-setters and osteopaths have no misgivings, and habitually postulate the existence of subluxation of the ilium as a pretext for mobilizing the joints of the lower back. Confusion of this sort can spring only from great individual variations in the criteria held to justify this diagnosis. When tenderness "over the joint" suffices, strain is found to occur in a fair proportion of all patients with backache; but when this diagnosis is restricted to cases showing a positive response to one or more of the tests set out below, the fraction is found to be very small. This paper seeks to show how a diagnosis of sacro-iliac strain may be limited to cases in which the pain arises in the sacro-iliac ligaments.

Incidence.—Adherence to the diagnostic standards described below enabled the presence of sacro-iliac strain to be determined in 3 out of the 420 patients with symptoms referable to the lumbo-sacro-gluteal region seen in the physiotherapeutic department of St. Thomas's Hospital during the past two years. During the same period I have also seen two such cases in private practice. Hence the frequency of sacro-iliac strain as a cause of such pains is estimated not to exceed 1%. I have yet to see this condition affect a male patient.

Summary of Findings in a Series of Five Cases.

The following table gives the salient features of five patients who, between them, had suffered six "attacks" of sacro-iliac strain.

Occupation	Age at Onset	Cause	Parity	Length of History (Months)	Side	Pain on Waking	Pain referred to	Tender Area	Palpable Subluxation	Control by Corset
Housewife	41	?	0	8	R.	No	Thigh, leg, and heel	All over sacrum	No	Yes
Physical Training Instructor	21	Twist in mid-air while vaulting	0	3	Both	?			?	Not tried
Housewife	33	Childbirth	1	12	"	No	Iliac fossae	None	Yes	No
Masseuse	27	"	3	25	"	Yes	Hypogastrum	"Over joint"	"	Yes
"	21	?	0	3	"	No	Sacral only	"	"	"
"	22	?	0	1	"	No	"	None	No	"

All five were women of childbearing age. Recovery after three months' rest in bed was followed in one case by recurrence twelve years later during the first puerperium. Strain began after the birth of her third child in another patient—a treated congenital syphilitic. The influence of trauma seemed negligible: only one patient gave such a history, and then the injury appeared too slight to have done more than make manifest a laxity already in existence. In three instances the onset was gradual and no cause was discoverable. A feature common to all patients was the unusually large range of movement at the lumbar spine; this suggested that the sacro-iliac laxity formed part of a more widespread suppleness.

Symptoms and Signs of Sacro-iliac Strain

The outstanding symptom is a deep sacral ache, aggravated by exercise and relieved by rest; three patients were free from pain on awaking in the morning. Pain was referred to the lower part of the abdomen in two cases,

and to the thigh, leg, and heel in another. The fourth and fifth patients had a purely sacral ache.

No patient volunteered the information, but questioning after making the diagnosis elicited the fact that clicking followed by increased pain had been noticed in three cases. Two patients had realized that the pain could be eased by provoking another click, and had discovered methods of reducing the subluxation. One fixed her pelvis by standing with her legs crossed, and gave her trunk a quick twist; the other knelt with her thighs pressed against the abdomen.

The signs of sacro-iliac strain are as follows:

Pain on Stretching the Anterior Sacro-iliac Ligaments.—The anterior superior spines of the ilia are pressed apart while the patient lies supine. This test proved as reliable as any; for pain was easily provoked thus in four cases. In the fifth no pain was elicited by any tension put upon the sacro-iliac joint except rotation, but palpable subluxation occurred (see below). Since a negative response to this test appears to exclude the sacro-iliac joint as the source of pain with reasonable certainty, this manoeuvre suffices during the routine examination of the lower back. Renewed search for the further signs described below is necessary only when the examination of adjacent structures fails to disclose the site of the lesion.

Pain on Stretching the Posterior Sacro-iliac Ligaments.—The patient lies on her side, and the uppermost part of the iliac crest is pressed downwards. If the pressure is applied well forwards along the bone the posterior ligaments bear the greater stress. Pain was elicited thus in three cases; moreover, it was felt less certainly. Though this test is less delicate than that described above, it possesses the advantage of not pressing the sacrum against the couch, thereby obviating confusion between pain due to pressure on a tender area and that due to stretching the ligaments.

Pain on Attempting Forward Luxation of the Sacrum.—The patient lies prone, and pressure is applied centrally over the sacrum. This is a good test; it yielded a positive result in four cases and a doubtful result in the fifth.

Pain on Forcing Rotation at the Joint.—A rotation strain cannot be put upon the joint without also straining the lumbar spine or the hip-joint towards extension. Since the chief diagnostic difficulty lies in distinguishing between lumbo-sacral and

sacro-iliac conditions, this test has little practical value, though pain thus elicited was present in every case.

Signs of Sacro-iliac Laxity

Presumably strain is merely the early stage of laxity, before excessive movement becomes apparent. In three bilateral cases laxity was demonstrated; in one bilateral and one unilateral case only the signs of strain were present.

Palpable Subluxation.—As the patient lies prone the ilium is pulled backwards by the examiner's one hand about the anterior superior spine, while the other presses the sacrum forwards. This manipulation may succeed in producing palpable movement at the joint; if so, an unpleasant crunch occurs, reminiscent of the sensation produced by fractured bone-ends rubbing together. Three cases showed this sign.

Radiography during Subluxation.—This did not prove possible in any case, and the radiographic appearances were consistently normal. Sacro-iliac strain, therefore, is a diagnosis that can be arrived at only on clinical grounds. The fact that subluxation can be produced in the manner described above,

considered in conjunction with the way in which patients had learnt to achieve reduction, leads to the conclusion that the abnormal movement is towards posterior displacement of the ilium on the sacrum.

Tenderness "Over the Joint"

A glance at the diagram giving the relations of the sacro-iliac joint should finally dispose of the idea that tenderness of any structure accessible to the examiner's finger denotes tenderness of the sacro-iliac ligaments. Nevertheless, tenderness "over the joint" was present in three of the five cases, though the tender structure was clearly the sacral part of the sacrospinalis muscle. Evidently the movement apart of the sacrum and ilium puts lateral stresses upon the

Diagram of relations of sacro-iliac joints at first sacral level. A, Posterior superior spine of ilium. B, Sacro-iliac joint. C, Sacrospinalis muscle.

fibres of origin of this muscle, causing a series of minor tears in this position. Hence a chronic traumatic fibrositis is set up, and is the proximate cause of the tenderness.

Tenderness "over the joint" is in no sense a sign of sacro-iliac strain, for it occurs far more commonly in fibrositis of the lowest part of the sacrospinalis muscle and its sheath, in the absence of any sacro-iliac affection. A diagnosis of true sacro-iliac strain is made on grounds quite other than the existence of such tenderness, whose presence is to some extent confirmatory, but whose absence is without significance. As a rule, loosely made diagnoses of sacro-iliac strain can be shown to be incorrect by the simple expedient of infiltrating with a local anaesthetic solution the muscle fibres lying behind the joint. If cessation of pain for the duration of anaesthesia results the site of the lesion evidently lies in the muscle. The objection that it is possible to be mistaken as to the position of the point of a needle is met by the fact that no one can fail to perceive the wide difference between muscle and dense fibrous tissue both in the resistance they offer to the progress of a needle and in the degree of pressure needed for their respective infiltration.

Clinical Course of Sacro-iliac Strain

The strain in Case 1 had been present for eight months when this patient was first seen. A corset was worn for a year, and she is now symptom-free without a corset. The laxity in Case 2 at the age of 21 cleared up completely after rest in bed for three months. The recurrence at the age of 33, after childbirth, has now continued unchanged for twenty months in spite of corsetry for the past eight months. Arthrodesis will be performed as soon as the patient can arrange to leave home. The laxity in Cases 3 and 5 is adequately controlled by a corset, which is still being worn. It is obvious that progress is being made towards freedom from pain in the absence of corsetry. The laxity in Case 4, though considerable in degree and in the amount of disability present, had improved so much after only one month's corsetry that this could be discarded for several hours a day without ill effect.

Treatment

The sacro-iliac is like the acromio-clavicular joint in that no muscle spans it; hence each relies for stability on its capsular ligaments alone. Mobilization of the joint leads to further overstretching and increased pain; indeed, the stresses put upon the joint by its mere clinical examination temporarily aggravate the symptoms. The fact that mobilization has cured "sacro-iliac strain" by supposedly adjusting the position of the ilium on the sacrum is in itself strong evidence that such strain was not present. All the manipulations calculated to move the ilium on the sacrum, as anyone who watches an osteopath can see, stretch or rotate the lumbar spine. Hence cure by mobilization suggests that the pain had a lumbar origin.

In true sacro-iliac strain, then, stretching the joint makes the patient worse. Immobilization is required, and is best obtained by a corset that holds the ilia firmly against the sacrum. It should be worn day and night until the pain on waking disappears; thereafter it need be worn only by day. After several months, if full relief has been attained meanwhile, the patient may try increasing periods up and about without the corset. Throughout she should be warned to do nothing that hurts, and to rest at once if pain begins. Since no muscle controls movement at the joint, exercises are contraindicated; for they can serve only to strain the ligaments further. Since a laxity absent for twelve years reappeared after childbirth in one case, it is evidently wise to prescribe adequate corsetry for several months before and after the confinement as a prophylactic measure in patients who have suffered from true sacro-iliac laxity in the past.

When repeated subluxations add to the patient's pain she should be shown one or other of the methods of reduction already described. Attempts at forcing by the practitioner are unwise, in so far as they are at best only momentarily successful; they are more apt to result in a prolonged increase in the symptoms.

Corsetry and the avoidance of all activity that sets up pain proved successful in four out of the five cases cited here, and progress towards full relief without a corset has been, or is being, achieved. Patient No. 2, though waking symptom-free, found a corset useless to prevent the regular onset of pain about two hours after rising. Since prolonged rest in bed—the only other conservative treatment—is impracticable, arthrodesis will be performed.

Discussion on Aetiology

When a ligament the tension on which is not under muscular control has been sprained, any overstretching thus caused is permanent. For example, it is a commonplace that lengthening of the cruciate ligaments of the knee, or of the capsule of the acromio- or sterno-clavicular joints, persists indefinitely. Now the sacro-iliac joint is not under muscular control; yet its laxity appears not to be due to injury, not to affect men, usually to be bilateral, to have some connexion with pregnancy, and to be recoverable from completely. These facts suggest that the cause is non-traumatic, general, peculiar to women, and temporary. It is interesting, therefore, to speculate on the possibility of an endocrine element in the aetiology of sacro-iliac strain. Evidence of very slight lengthening of the ligaments towards the end of pregnancy has been demonstrated and measured radiographically. The existence of a special hormone of the corpus luteum—relaxin—has been suggested to account for this change, which is strikingly large in some animals. Hence, sacro-iliac strain may in the future come to be regarded as due to a temporary over-

DEC. 13, 1941

CONGENITAL ARTERIOVENOUS ANASTOMOSIS

secretion of this hormone, and thus in essence a medical rather than a surgical condition. An increase in the distance between the bones at the symphysis pubis, had it been visible on the radiographs, would have afforded valuable confirmation of this hypothesis, but was not in fact demonstrable.

My thanks are due to Mr. R. H. Young, my senior colleague at St. Thomas's Hospital, for his advice and for assistance in the diagnosis of two of the cases.

CONGENITAL ARTERIOVENOUS ANASTOMOSIS

BY

ARTHUR G. WATKINS, M.D., M.R.C.P.
Physician in Children's Diseases, Cardiff Royal Infirmary and
Llandough Hospital

Cases of congenital arteriovenous anastomoses in the limbs have been recorded by Reid (1925), de Witt Lewis (1930), Holman (1937), and others. Most of these, however, had an associated surface naevus, which was not present in the following case. The existence here of an arteriovenous communication is suggested by the slowing of the pulse after reducing the arterial flow through the anastomosis by occlusion of the right common femoral artery. Lewis and Drury (1923) suggest this fall in rate is vagal in origin.

Case Report

The patient, a girl aged 8, was an only child of healthy parents, who stated that since birth they had noticed that their child's right leg was bigger and hotter than the left. Apart from this the limb had given no trouble until two days before she was seen, when a "milky discharge" had appeared in the right groin. This was painless and did not follow any known injury. She had always been healthy except for scarlet fever, measles, and an attack of catarrhal jaundice.

When she first attended the out-patient department the girl's general condition was good apart from discomfort from the discharge. This came from a pin-point opening on the inner side of the right thigh, about the apex of Scarpa's triangle, and was quite profuse, 1 c.cm. being easily collected in a test-tube. Her clothing, though changed about two hours previously, was soaked. There was no obvious sinus and no reddening or thickening of the skin. Her right leg was larger and warmer to the touch than the left.

She was admitted to the ward for further observation, but by the following morning the discharge had ceased; it never recurred in spite of massage and exercise of the limb, nor could we find the opening through which it had come. She had never had this trouble previously, nor has it recurred since she was seen last April. The fluid collected was reported on by Dr. Gough as follows: "The appearance is that of a pale yellow milky opaque fluid with a clot stained faintly pink on standing. The cell count is 1,600 per c.mm., all lymphocytes. No organisms were seen, and nothing was grown on culture. The fluid contains only a little fat. It is not 'chyle,' but may be a fluid from a lymphangiectasis."

Examination of the right leg showed that throughout its whole length it was larger and warmer to the touch than the left. The measurements of the limbs and bones were as follows:

	Right Leg	Left Leg
Iliac crest to heel	29½ in.	27½ in.
Iliac crest to tibial spine	16½ in.	15 in.
Tibial spine to big toe (foot extended)	17½ in.	16½ in.
Length of foot	8 in.	7½ in.
Maximum circumference of thigh	14 in.	12 in.
Maximum circumference of leg	9 in.	8½ in.
Maximum circumference of both tibiae on single film	12½ in.	11 in.
Radiograph of tibia	2½ in.	2 in.
Length of tibia	3¼ in.	11/16 in.
Breadth of head of tibia	1¼ in.	1¼ in.
Breadth of shaft of tibia		
Breadth of shaft of fibula		

Pulsation was felt behind the inner border of the right tibia almost throughout the length of the bone, and there were several palpable and pulsating vessels around the inner aspect of the

right knee-joint. The limb surface in the upper thigh area was shiny, with some distension of the superficial veins extending to just above the iliac crest. No demonstrable oedema of the limb was observed. The internal saphenous vein was palpable and visible along its course from the internal malleolus to the inner side of the thigh; the skin was grooved over it, and it was patent throughout. There was no collection of enlarged superficial vessels in the skin.

Pulsation in the dorsalis pedis artery was equal to the touch in both feet, and the systolic pressure in both legs was 130 mm. Hg. The blood pressure in each arm was 110/80 mm. Hg. Occlusion of the right common femoral artery slowed the pulse after an interval of about 6 beats by 10 to 15 beats a minute, with quickening soon after release. Occlusion of the left artery was without effect on the pulse rate. No other vascular abnormalities were noted, and the heart was normal in size. A radiograph of the right tibia showed no grooving suggestive of erosion by enlarged vessels.

Surface temperatures were not taken, but daily groin temperatures were on the average 0.4° to 0.8° higher in the right groin than in the left. Repeated observations in which the skin was felt showed the temperature to be consistently higher on the right side throughout the whole leg.

Discussion

The unusual and puzzling feature of this case was the milky discharge, and no reference to a similar happening has been found in the literature. Unfortunately this cleared up so quickly that we were unable to make full observations on it, but its presence pointed to an increased flow of lymph in the limb. The close embryonic relation between lymphatic vessels and veins, which are both derived

from a common capillary plexus, may have produced a lymphatic developmental disturbance with increase in the lymph channels, or the greater lymph flow may simply have been the result of an increased blood supply to the limb. No oedema of the limb was present when the patient was first seen, and we do not know whether there had been any before the discharge.

The most striking clinical feature of these cases is the increased growth of the limb, affecting bones and soft parts. Paterson and Wyllie (1925) suggest this is due to an increased vascularity at the growing ends of the tibia and femur. Experimental section of the sympathetic nerves of limbs of kittens as described by Harris and Wright (1930), although producing a greater blood supply, did not increase their growth. When the cervical sympathetic nerve and ganglia were removed in a rabbit's ear some increase in growth was noted after 100 days, and those authors suggest that it may be the higher temperature of the limb that acts as a stimulus.

The exact cause of the hypertrophy is still far from clear, and the presence of the lymphatic discharge in the above case must remain unexplained until a recurrence of the discharge allows later investigation, or further cases have been observed.

My grateful thanks are due to Sir Thomas Lewis for the interest he has taken in the case and the help he has given in writing these notes.

Medical Memoranda

Isotonic Glucose Solution in the Treatment of Fibrositis

J. H. Kellgren (1938), in an account of referred pain arising from muscle, recommended the infiltration of a 1% solution of novocain into the tender spots. The success attending this method of treatment is no doubt the reason for its adoption by an increasing number of observers. Various proprietary preparations of cocaine, under different names, have since made their appearance, and all seem equally efficacious. They all, however, labour under a common disadvantage in their liability to produce general as well as local effects, to say nothing of the risk of the formation of a habit, which might easily occur. Complaints of a "muzzy" sensation after injection are by no means uncommon, while in susceptible individuals the systemic disturbances thus evoked may be decidedly unpleasant.

Kellgren mentioned that in instances in which novocain infiltration abolished the symptoms this effect often outlasted the actual anaesthesia and was more or less permanent. This can readily be confirmed by anyone who has used this treatment, and the question naturally arises whether an injection solution possessing local anaesthetic properties is really necessary.

An isotonic solution of glucose seems to have very much the same effect, and I have been using it for some time with equally good results. A 5-c.cm. syringe fitted with a very fine needle is employed. The parts are carefully palpated in order to find the exact spot from which the pain radiates. The patient will usually flinch when the finger presses the tender area, and inquiry should be made whether the pain "shoots" along the limb or part in any given direction. It must be emphasized that the mere presence of pain in a limb or elsewhere is not in itself a sufficient indication for the injection unless it can be clearly shown that the source of the pain is a palpable tender spot. Diffuse pain in a limb without localized tenderness should be treated in other ways.

When the tender spot has been found it is well to mark it with a skin pencil and then continue the search for similar areas. These will no doubt be found and marked in like manner.

With the syringe charged with 5 c.cm. of isotonic solution of glucose the fine needle is introduced for about an inch into the marked spot and 1.5 to 2 c.cm. is slowly injected. If the patient experiences some pain radiating from the site of injection it is pretty certain that the correct spot has been chosen. The remainder of the fluid in the syringe can then be distributed among the other spots that have been marked. Usually three injections are enough.

Nova et Vetera

DR. GEORGE BIRKBECK, 1776-1841

December 1 marked the centenary of the death of Dr. George Birkbeck, the eminent philanthropist and physician. He was born at Settle in Yorkshire on January 10, 1776, the son of a well-known merchant and banker. He studied medicine first at Leeds, and then in London, where he became a pupil of the celebrated Matthew Baillie, and lastly in Edinburgh, where he qualified in 1799 with a thesis on the blood. Shortly afterwards he succeeded Dr. Garnet as professor of natural philosophy at Glasgow, where he instituted a free course of lectures on philosophy for the labouring classes. This work met with remarkable success and formed the basis of a system of mechanics' institutes to which he devoted most of his life. He left Glasgow in 1804, and after lecturing in Birmingham, Liverpool, and Hull, settled in London, where he soon acquired a large practice. In 1822 he helped to found the London Mechanics' Institute in Chancery Lane, to which he lent £3,000 for the erection of a lecture theatre. He was made director of the institute, to which his name was given, and held this office until his death. A brief memoir of him by Dr. Henry Clutterbuck was published in the following year.

THE FOLK-LORE OF ALCOHOLISM

In a recent paper (*Brit. J. Inebriety*, 1941, 39, 30) on this subject Dr. J. D. Rolleston remarks that with the exception of Hovorka and Kronfeld, who devote some pages to it in their work on comparative folk-medicine, no writers, to his knowledge, have dealt at length with folk-lore in relation to alcoholism. He has therefore collected the folk-lore of this condition, as he has recently done in the case of pulmonary tuberculosis and other diseases (see *Journal*, 1941, 2, 417). His paper deals with the nomenclature, popular phraseology, superstitions, and leechcraft connected with alcoholism, the term "leechcraft" being that commonly employed in the language of folk-lore to indicate popular methods of prevention and cure. In his paper on "Alcoholism of Inebriety in 1926 (see *Journal*, 1926, 2, 702) he had drawn attention to the numerous synonyms for bibulous and inebriated persons both in Greek and Latin as well as in English, which, according to Roget's *Thesaurus*, contains about seventy such terms, only a minority of which could be regarded as slang. In a recent perusal of Farmer and Henley's work on *Slang and its Analogues* he had found over 600 terms for the substantive and verb "drink" and various forms of alcoholic intoxication. The number of slang synonyms connected with alcoholism was only exceeded by those of even greater popular interest—namely, "money" and words connected with the anatomy and physiology of the generative organs in both sexes. Popular interest in the consumption of alcohol, especially in excess, was further demonstrated by the great variety of similes and proverbs connected with excessive drinking. The number of superstitions and popular errors associated with alcoholism was legion.

Dr. Rolleston classified the folk-lore remedies for the prevention and cure of alcoholism as follows: (1) animal remedies, many of which were to be found in Pliny; (2) plant remedies, of which the chief were cabbage (highly esteemed by Cato the elder), almonds, and betony; (3) mineral remedies, including the agate, amethyst, and pumice stone; and (4) water. Unlike pulmonary tuberculosis, for which there were many patron saints, alcoholism had few religious associations apart from Dionysus or Bacchus in classical antiquity.

Reviews

CANCER IN COTTON WORKERS

Mule Spinner's Cancer: Epithelioma of the Skin in Cotton Spinners. By E. M. Brockbank, M.B.E., M.D., F.R.C.P. (Pp. 36, 4s.) London: H. K. Lewis and Co., Ltd., 1941.

Epithelioma, or cancer of the skin, occurs in a number of industries, especially those in which tar or mineral oils are handled. To-day it is probably the commonest notifiable industrial disease, with the highest mortality rate. In 1918 165 cases were notified to the Factory Department, of which 21 were fatal; of these cases 58 occurred among cotton mule spinners, with 12 deaths. In 1940, 41 mule spinners were known to have contracted the disease, and 20 deaths were reported. These facts speak for themselves, and the short illustrated monograph issued recently from the pen of Dr. E. M. Brockbank is therefore all the more welcome, and is a valuable contribution to the literature on the subject. The author's experience of this occupational disease extends over many years in his capacity both as a medical referee for industrial diseases and as chairman of the Manchester cancer research subcommittee since its foundation in 1925. With such unusual opportunities for studying the problem of mule spinner's cancer it is no wonder that this book is a mine of information, most of it of a severely practical nature. Its contents should be fully known to all those whose work brings them in any way into contact with the cotton industry, masters and men as well as the medical profession. As the author claims, if systematic preventive measures are generally adopted the incidence of the disease should diminish greatly and eventually it should disappear completely.

Dr. Brockbank discusses the history of the disease with special reference to its incidence in the cotton mills of Lancashire. It is a matter of considerable significance that the University of Manchester established a special research unit to deal with the problem, and the work of Twort and others in this connexion is well known. Perhaps the most interesting parts of the book are where the author discusses the causation of scrotal cancer, the scrotum being that part of the body most frequently affected, and outlines certain preventive measures. It is obvious that the author has an intimate knowledge of the industry and has based his observations on close investigation of the various processes within the actual factory. His description of the mule spinning machine, for example, is a model of clarity. Among the preventive measures advocated are regular periodic medical examination of operatives; talks with the men on personal hygiene; propaganda by means of lantern lectures and handbills; and careful selection of oils so that only those with the lowest carcinogenic properties are used in the industry. There is never a better case for setting up factory medical services than where a specific health hazard exists. In our view more could have been made of this point by the author, because if individual firms in the cotton industry are not large enough to appoint their own medical officers in a whole-time capacity, or are anxious to have them in a part-time capacity, there appear to be good economic and humanitarian grounds for the industry itself to make special appointments of one or more whole-time doctors.

In these days when industrial health is of such vital importance to the national effort it is refreshing to know that senior members of the profession outside the ranks of industrial medical officers are taking an active interest in the problem. More of this practical interest is urgently wanted from both medical and surgical specialists as well as from members of the research and teaching units

attached to our main hospitals. The example of Manchester University, which incidentally is one of the very few in this country having on its staff a lecturer in industrial hygiene, is one to be followed by others; an example not only of the practical application of medical research to factory needs but of a policy carried out with the close collaboration of the actual industry concerned.

REVIEW OF BIOCHEMISTRY

Annual Review of Biochemistry. Edited by James Murray Luck, Associate Editor, James H. C. Smith. Volumes IX and X (Pp. 341 and 692, 2/6 each volume.) (California: Stanford University P.O., Annual Reviews, Inc.; London: H. K. Lewis and Co., Ltd.)

In these two volumes we observe the influence of wartime conditions in tending to remove the international character from a scientific publication hitherto noted for that quality. There is, however, no fundamental departure from customary form and standard, nor is there any blurring of the clear picture which the publication has yearly presented of biochemical progress.

To readers of this *Journal* the 1940 volume affords a greater proportion of interesting material than most of its predecessors; three contributions have very direct bearing on clinical work—one, in fact, being entirely devoted to the clinical applications of biochemistry. This contains a useful and timely survey of tests introduced into service in recent years, but which have called for extensive study in order that their significance might be properly defined. While the chapter on the application of microchemistry to biochemical analysis will concern only the laboratory worker, that by Prof. Dodds and Dr. Dickens on the biochemistry of malignant tissue has a distinctly wider appeal, for it is out of such authoritative evaluations of the literature that most of us must gauge the extent to which scientific research is penetrating the cancer problem.

The striking claim that the proteins of cancer tissue are characterized by the presence of amino-acids of "unnatural" configuration receives critical treatment in the article just mentioned, and it is further examined in more than one connexion in the current volume. The evidence now accumulated seems to dispose of the validity of the original contention. In the past the *Review of Biochemistry* has provided some remarkably able contributions in the hormone field, but none have surpassed that of P. C. Kendall in the latest volume for its combination of clarity and conciseness. The hormones of the adrenal cortex receive rather special attention, in aspects ranging from their chemistry and physiological effects to their clinical applications.

The value of the current volume could not be fully emphasized without reference to the chapter on nutrition—a topic which now challenges the interest of the whole community. Here is summarized in very readable form the results of various big-scale investigations carried out in the U.S.A., designed to give an accurate appraisal of the nutritional status of different sections of the population. The lessons to be derived from such studies are clearly of immense importance to all engaged in tackling the food problems of our own country.

IMPERFECT MAN AND HIS FUTURE

Medicine and Mankind. By Arnold Sorsby. (Pp. 246; illustrated, 12s. 6d. net.) London: Faber and Faber, Ltd., 1941.
Man: The Mechanical Midget. By G. H. F. Labrook. (Pp. 251, 10s. 6d. net.) London and New York: The Macmillan Company, 1941.

At this crisis in world affairs it is not surprising that the application of biology to sociology, using both terms in their widest sense, should make a wide appeal. The two

books before us are concerned with the influence of the manifest imperfections in man's physical and mental equipment on the future of civilization; but here their resemblance ends. It is curious that two authors starting from the same premises should reach such contrary conclusions. Mr. Arnold Sorsby's *Medicine and Mankind* is a sober review of the nature of disease under the headings of "The Ill-formed Body," "The Ill-balanced Body," "The Abused Body," and "The Assaulted Body"—titles which indicate his method of approach. Then follow chapters on treatment by individual and collective measures, leading up to a consideration of social achievements and frustrations. The teaching of Galen stressed the perfection of the body; later authorities laid emphasis on its corruptibility; both these views postulated an unchanging body in a changeless environment. To-day we visualize the body as in an unstable physico-chemical equilibrium, constantly responding to the shifting equilibria of the outer world. Medicine must take into account both the internal structure of man and his external environment. The author recalls the views of Heraclitus 2,500 years ago that everything is in a state of "becoming"; we might add that Bergson's modern revival of that philosophy in a forcible form has been forgotten all too soon. The whole argument is couched in such language as to appeal to the ordinary educated reader; technical jargon has been skillfully avoided, while the illustrations and graphs are a decided help. Apart from his fears as to a decline in the population of the civilized world, Mr. Sorsby's conclusions are on the whole hopeful, as indeed the achievements of man justify, despite recurrent setbacks due to the cave-man who is still always with us. The bearing of mental activities on health and disease and their derangements are deliberately excluded from this survey because the author felt it impossible to do justice to such a complex subject within the compass of his book. Nevertheless he has produced a thought-stimulating piece of work, with a forwardly directed gaze which faces the problems of the future courageously.

Dr. G. H. Estabrooks is an anthropologist and not a medical man. The jaunty and jocular style of his *Man: The Mechanical Misfit* accords ill with his pessimistic conclusions. He is convinced that man began to deteriorate from the time he adopted the upright position. He appears to look to unopposed action of natural selection as the only remedy for the parlous state into which mankind is falling. This book is a positive mine of inaccurate information.

SCHIZOPHRENIA IN CHILDHOOD

Schizophrenia in Childhood. By Charles Bradley, M.D. (Pp. 152. 10s. 6d. net.) New York and London: The Macmillan Company. 1941.

The Emma Pendleton Bradley Home admits "difficult" children with mental and physical disabilities, and Dr. Bradley, as medical director, has had a full opportunity of studying children's psychological reactions over a long period. The subject he has chosen for his monograph is a difficult one, for schizophrenia as a whole is still a battleground of theories out of which, unfortunately, all too little practical achievement has emerged.

Schizophrenia is a fairly common disease of youth but not of childhood; indeed, some authorities declare that the onset of puberty is necessary for its development. This, however, is apparently not true, for in the literature, which is amply reviewed in this book and correlated with the author's own experience, cases are described which are now sufficiently numerous to establish what the author in his

last chapter calls a "practical concept of childhood schizophrenia." This chapter, in fact, admirably sums up the whole of the systematic discussion of the subject which makes up the rest of the book. Schizophrenia to fit in with this concept must occur in childhood—that is, before the age of 13—and must be severe enough to constitute a psychosis, for many "schizoid" traits may be observed in children who are certainly not psychotic. The appearances of the disease will differ from those in the adult by reason of the child's restricted mental development and of the fact that his mind is developing all through the progress of the disease. The author suggests as a short definition "a rare but severe distortion of the personality, peculiarly distinguished by a diffuse retraction of interest from the environment."

Many factors may be cited as having causative significance, but none of them is found to be universal or even statistically valid, and we must admit that we do not know the cause. Primary symptoms are extreme seclusiveness, excessive day-dreaming, regression of personal interests, bizarre inappropriate behaviour. Autistic thinking and dissociation, emotional blunting, and intellectual deterioration are less marked than are these symptoms in adults. Outbursts of temper, negativism, and psychomotor activity are secondary to thwarting of primary symptoms. Clear-cut examples of the four adult types are not seen in childhood, and it is probably better to describe acute and chronic types. Laboratory tests, whether pathological, neurological, or psychological, are not helpful, and diagnosis depends on the combination of symptoms. Treatment, whether by psychotherapy, shock therapy, or other means, is uniformly disappointing, and the prognosis is bad.

This is a well-documented review of a difficult subject, with a good bibliography, and it may be confidently recommended to the attention of all psychiatrists and paediatricians.

Notes on Books

Plant Science Formulae, by R. C. McLEAN and W. R. IVIMY COOK, is described as "A Reference Book for Plant Science Laboratories (including Bacteriology)," but the bacteriologist will find only a few very simple stains and culture media described which fall within his province. Mycology and botany are much more fully served, as is to be expected both from the main title and from the fact that both authors are botanists. The book consists entirely of formulae and practical instructions, and those concerned with fixing, embedding, museum work, and photography have wide applications and will be generally useful, as are such things as the log tables, a chapter of physical and chemical formulae and equations, and a list of scientific suppliers. Most original and useful of all is a chapter entitled "Workshop Receipts," which gives instructions for painting black-boards, cleaning mercury, silvering glass, making putty, size, and polarity paper, and many other useful things not often found in books. The publishers are Macmillan and Co., and the price is 7s. 6d.

Dental Materia Medica, Pharmacology and Therapeutics, by Prof. W. J. DILLING and Mr. SAMUEL HALLAM, has now appeared in a new edition (Cassell and Co., 13s. 6d.). The drawback of this book is that it attempts to cover almost the whole field of materia medica, and gives insufficient attention to the information which the dentist really requires. There is no mention of the sterilization of syringes, and no discussion of the difficulties of sterilizing solutions of procaine, except to say that solutions of procaine can be boiled, which many consider unsafe. Nor is there any mention of the danger of boiling adrenaline when diluted unless precautions are taken to keep the reaction acid. There is no mention of the increasing appreciation of the value of percaïne, or indication that it stands out in usefulness above other local anaesthetics. These and other similar points are of great importance for the dentist.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 13 1941

CERTIFICATION AND NOTIFICATION

The winter session of the General Medical Council which has just been held draws attention once more to the thorny question of certificates, especially to those which are signed carelessly or in a misleading manner. Of late, our correspondence columns have borne witness to the growing irritation among doctors at the multiplicity of forms they are called upon to sign. And last week a correspondent in our contemporary recorded that he had had to sign a certificate so that a child with congenital dislocation of the hip could be supplied with a rocking-horse. Those who have to carry this additional and vexatious burden deserve our sympathy. But however the demands for certificates may grow they must be signed with good faith, care, and exactitude. In the *Journal* of April 19 of this year we printed a warning notice issued by the General Medical Council on the signing of certificates. As the notice stated: "Unverified assertions made by the patient himself, personal opinions as to his fitness or unfitness for various forms of service, or for particular hours of work, and other statements not founded on a careful examination of the patient immediately before a certificate is given, or supported by ascertained facts or conditions, are not proper material to support a certificate signed by a registered medical practitioner as his testimony to facts within his professional knowledge." The notice went on to emphasize that a certificate should be granted *only on medical grounds*, and from the practitioner's personal knowledge of the health and physical condition of the applicant at the time of granting the certificate.

These are clear and, indeed, obvious desiderata. Nevertheless we have good reason to believe the military authorities have been disturbed by numerous instances of apparent laxity in the granting of certificates to soldiers. At Liverpool Assizes last month a practitioner was sentenced to four years' penal servitude for issuing a number of deliberately untrue certificates to members of H.M. Forces. Such an offence, apart from gravely infringing the professional code, is a serious obstruction of the war effort and rightly called for the stern comment of the judge in passing sentence. Last week in the House of Commons the Minister of Labour and National Service, in reply to a question, said that he was prepared to take ruthless action against anyone falsely certifying men unfit for military service. But it is less in the deliberate untruth than in the careless and inaccurate statement that harm is being done. All practitioners would do well to search their own hearts on this score. For example, serious interference with war production may be caused by certifying men unfit for night work on apparently very slender medical

grounds. A list could easily be made of minor evasions from various forms of national service and wartime restrictions. There is the fire-watcher who seeks exemption for a trivial disability; the housewife who wangles extra milk for an alleged illness; the soldier who wants an extra day's leave. In many such cases the granting of a certificate may be perfectly justified, but in far too large a minority it is not. The certifying doctor must be sure of his grounds and remember that an unjustified certificate not only causes a weakening of the war effort but exposes him to the jurisdiction of the General Medical Council.

Three penal cases concerning irregular certification were considered at its recent session, and some of the points arising therefrom are worthy of comment. One defence suggested that the document in question was not a certificate in that the words "This is to certify" or some such phrase did not appear on it. In its warning notice to the profession the G.M.C. speaks of "any such certificate, notification, report, or document of a kindred character which is untrue, misleading, or improper." Clearly, then, any written statement about a patient's health which is backed with the authority of the signature of a medical man as such falls into the same category, however it may be worded and whatever title it may bear. Another line of defence was that the document did not contain any statement that the patient had been examined. Whereas the official certificates used in relation to national health insurance must state categorically that patients have been examined on a particular day, other forms of certificate, less precisely drafted, are in common use, and in these the question of whether such certificates are misleading may, and often does, arise. The party for whose information the certificate is issued is entitled to assume that the facts cited therein are within the doctor's own knowledge. It should never be the practice for a doctor to give a certificate for the substance of which he relies on the statement of someone else, especially when members of the Forces are seeking extension of leave or exemption from service on medical grounds. "What the soldier said" or "what the butler saw" is not evidence. Failure to keep proper records or books of accounts is not professional misconduct, but its inconvenience to practitioners who may need evidence from such records or accounts for their assistance in legal or other proceedings was illustrated by another case before the Council in which the charge was not found proved. It is a matter of elementary prudence to keep what is generally known as the "day book," in which the name and address of the patient and such details as prescriptions given are recorded under the exact date of the visit. Such a serial record of work done provides evidence that cannot be disputed.

In addition to signing certificates the practitioner has a statutory duty, under various Acts of Parliament, to notify certain events. A practitioner charged with failure to notify the medical officer of health of his district, as required by the Puerperal Pyrexia Regulations, 1939, in a case attended by him in a maternity ward on May 26 and subsequent days, stated in evidence that he never notified cases of puerperal pyrexia occurring in his hospital practice, although he always did so in his private

practice. His patient had obstructed labour, and he performed Caesarean section seven hours after admission to hospital. She suffered from thyrotoxicosis and dilatation of the heart, and later developed acute pneumonia and died on the seventh day after delivery. Although over most of the period the temperature was raised considerably, the practitioner did not consider that his patient suffered from a septic condition arising from the confinement. He had not, however, made any bacteriological examination of the lochia or of the blood. Facilities for making these examinations were available in his district. The G.M.C. found that the facts alleged against him in failing to notify had been proved to its satisfaction. The Minister of Health, in Circular 722, issued in 1926, when notification of puerperal pyrexia was first introduced, and again in Circular 1765, issued in March, 1939, sought "to impress upon all those concerned with the administration and clinical conduct of maternity institutions that the presence of a febrile condition, however slight in degree, in a patient or member of the staff should be considered as liable to give rise to an outbreak of virulent infection." Circular 1765 also stated that "if notification of puerperal pyrexia is to have practical value it should be early and complete. It should be followed by investigation into individual cases and by intensive study of the causation and course of outbreaks of infection, whether in domiciliary or in institutional practice." These regulations under the Public Health Act, 1936, are made solely in the public interest. Regulation 2 defines puerperal pyrexia as "any febrile condition occurring in a woman within twenty-one days after childbirth or miscarriage in which a temperature of 100.4° F. or more has been sustained during a period of twenty-four hours or has recurred during that period." Whatever may be the medical attendant's belief as to the causation of this rise of temperature in any specific case, it is his plain duty to notify every case and to take the steps necessary to establish a definite diagnosis by modern bacteriological methods, so that the newer forms of treatment are not denied to his patient and that the community may be protected against the further spread of streptococcal infections when these have been found to exist.

It is much to be hoped that practitioners—in their own interest as well as in that of the public—will make themselves fully acquainted with their legal obligations and take heed of the obvious lessons that can be learnt from the cases recently before the G.M.C. and recorded in the *Supplement* to this *Journal*.

PRUNING THE PRESCRIPTION

In the more spacious pre-war days cases of excessive prescribing were not infrequently brought before Panel Committees, but the fault was generally regarded as venial, and only in the worse examples was any severe penalty imposed. The importance which patients, insured or not, attached to drugs or other medicaments as an outward and visible sign of medical treatment was always remembered. Unusual demands for drugs, even the use of more expensive preparations when cheaper ones would suffice, were regarded as an unwarranted

trespass upon national health insurance funds, but not as a misdemeanour from the point of view of national economy. With the nation at war, however, the situation is entirely altered, and what was an excusable indulgence becomes a grave dereliction of duty. Our attention has again been drawn to the great need for economy, especially in the phenol derivatives and, linked closely with those, in alcohol, glycerin, glucose, mercury salts, and liquid paraffin.

It has been an unhappy experience during this war to find, with regard not only to drugs but to foods and other commodities, that when the public is urged to practise restraint in buying some particular article many people immediately make a run upon it, with the consequence that sometimes it disappears from the market altogether. It is only necessary to say that there is a shortage of some commodity, and forthwith individuals, foreseeing rationing and control, lay in exceptional stocks. That has been the experience with drugs, so that instead of a hoped-for slackening in requirements there has been an increased demand, and the slender margin of supply has been obliterated. When the Therapeutic Requirements Committee of the Medical Research Council mentioned that economy in liquid paraffin was desired the effect was actually to increase the call for that substance.

One economy now specially urged is in the use of aspirin and the salicylates generally. There is believed to be a considerable amount of aspirin addiction in this country. We hesitate to give the quite astonishing figures quoted to us by a well-informed official concerning the amount of aspirin regularly taken by young women in Government offices. It seems to be as usual to swallow an aspirin tablet as it is to use a cosmetic. Purchases of aspirin and kindred remedies over the counter without a prescription may have to be regulated, but meanwhile medical practitioners can help to set an example by exercising some restraint in ordering such drugs, putting down only 5 grains, for instance, if 5 grains will serve, instead of the accustomed 10. The difference in the individual case is negligible, but it must always be multiplied by the thousand or hundred thousand of similar cases and thought of in terms of shipping space or the use of a particular substance for war needs. Practitioners might also consider whether they are ordering larger quantities of mixtures at a time than they need. In Scotland the standard mixtures are made up in 6-oz. bottles, but in England in 8 oz. It has been possible here and there to cut down the size of containers, also to limit the variety of sizes offered. One manufacturer formerly used to put up aspirin in twenty-five different sizes of packing; he now puts it up in four, with no particular disadvantage to the purchaser. Unfortunately one cannot, by the wave of a glass rod, alter the size of the medicine bottle. It is true that the bottle need not be filled up to the cork, but, there again, there is supposed to be some obscure value in the full bottle brought back from the drug store or dispensary. The public would probably not object to a smaller bottle, but a bottle which was only three parts full would have a sadly depreciated merit in their eyes. All that can be done in this matter is to appeal to the public spirit of the medical profession. If any

doctor still insists on exceeding his real requirements and rejecting proffered substitutes—and there is no shortage of articles for which there is no substitute—we must be left, for the present, to his conscience. Such action makes inevitable a control imposed from without, which will have to be endured not only by those who have put their own interests to the front but by those who have loyally responded to the appeals made to them. But if the profession does incline sympathetically to official guidance in this matter there will be enough drugs to go round. On the other hand, if any considerable number of practitioners rush in to stake out excessive claims difficulties will at once arise and some sort of control may become necessary—an expedient which, in spite of the supposed love of Whitehall for bureaucracy, the Ministry of Health is anxious to avoid. There is believed also to be a good deal of wastage of drugs in hospitals and other institutions, and the Ministry has done well to circularize not only the medical but the nursing staffs of E.M.S. hospitals, and, we believe, of the municipal hospitals as well.

The War Memorandum prepared some time ago by the Therapeutic Requirements Committee and issued by the Medical Research Council on "Economy in the Use of Drugs in Wartime," followed as it has been recently by the *National War Formulary*,¹ as well as by the latest Addendum to the *British Pharmacopoeia*,² which was compiled with the war situation in view, gives indications as to the "limited" drugs, the replacements available, and the economies which may be practised. With these the practitioner should have little difficulty in reconciling his duty as a citizen with his duty to his patient.

DERMATITIS FROM NAIL LACQUER

Little has been heard in this country of dermatitis due to cosmetic preparations for the nails. Cuticle removers, which often have for their active ingredient liquor potassae suitably diluted, are sometimes known to give rise to onychia, but the manufacturers are well aware of this risk and often make their product so weak as to be rather ineffective. But in America during the last few years a good many cases have been recorded of dermatitis due to the employment of nail lacquer, whether dyed or colourless. One of the first cases was reported by Sulzberger in 1937; in this the diagnosis was confirmed by positive patch tests. Palmer³ now reports nine cases in about a year. In each instance the dermatitis began on the face and only subsequently and much later spread to the peri-ungual skin. It appears to be caused by contact between the lacquered nails and the cheeks, chin, or eyelids. Recovery ensued when nail lacquer was discontinued, but resumption caused a relapse. Palmer made considerable efforts to discover the toxic agent in the lacquer and tried to secure the co-operation of one of the manufacturers, but without success. He was merely assured by the firm applied to that its product was above suspicion. Nail lacquers appear to be composed of four constituents: (1) a body, usually consisting of nitrocellulose with a resin; (2) a plasticizer, an oily body with a high boiling-point; (3) a solvent, which may be a ketone, an alcohol, or an ester; and (4) a dye—

but some nail lacquers are colourless. There is no evidence that the highly coloured lacquers which many women prefer are any more likely to give rise to symptoms than the colourless varieties. Although Palmer tested no fewer than twenty-nine different compounds with a view to discovering the toxic ingredient, his results were inconclusive. It can only be said that a few substances known occasionally to give rise to dermatitis in other circumstances may sometimes do the same when included in a nail lacquer. Such are formaldehyde, cresol, and turpentine. The use of nail lacquer appears to begin at an earlier age in America than it does here. Palmer states that girls of 5 years and upwards are found to use it, but as yet he has found no cases of lacquer dermatitis in children, or in women who lacquer their toe-nails, or in men who employ colourless lacquer for their finger-nails.

DEATH FROM MERCURIAL DIURETICS

The mercurial diuretics represent the most noteworthy advance in the treatment of dropsy since Withering rationalized the employment of digitalis. It is probable that they are still not widely enough used, more particularly in cases of left heart failure in which oedema and congestion are localized to the pulmonary circulation, and in which the presenting symptom is dyspnoea or cardiac asthma. With remedies so powerful as this it is not surprising that, as with digitalis itself, untoward symptoms occasionally occur. The older physicians were well aware of the accidents of diuresis and were wont to advise that the heart should be supported by digitalization before diuresis was encouraged. There is, however, nothing to suggest that mercurial diuretics increase the work of the circulatory system, apart from the mechanical effort of urination. The kidney, like the large bowel, acts as a condenser in which most of the large volume of fluid filtered out of the circulation is restored to it, and the mercurial diuretics act essentially by diminishing the efficiency of the recovery process. It is, in fact, the duty of the kidney to aid in conserving the internal milieu of the organism, and one of the dangers of diuretics lies in interference with this process. It is no light matter for the body, even the oedematous body, to adapt itself to a total loss of five litres or more of fluid a day—the resulting disturbance, both in the balance of electrolytes and in the partition of water between cells and body fluids, may express itself in symptoms of physical malaise and mental disturbance. These ill effects can to some extent, though perhaps not entirely, be avoided by regular examination of the blood plasma, more particularly for chloride, bicarbonate, and urea content; and biochemical tests of this kind are absolutely essential if mercurial diuretics are supplemented by a salt-poor diet or by acidifying agents. These biochemical disturbances give warning of their development, and in the hands of the careful physician they should never end fatally. Unfortunately they do not exhaust the dangerous potentialities of this form of treatment.

In a discussion at the annual meeting of the Association of Physicians of Great Britain and Ireland this year several speakers mentioned the occurrence of sudden death after treatment with mercurial diuretics, and a fully documented account of such accidents has now been published from American experience by Mary Tyson.⁴ She has collected the histories of five cases of fatal or almost fatal reactions to intravenous injections of mercurial diuretics; all of these were associated with nephrosis. The shock dose was never more than 1 c.cm., and in some cases only 0.5 c.cm. In every instance the intravenous injection was made slowly.

¹ *British Medical Journal*, November 8, 1941, pp. 656, 662.

² *Ibid.*, September 27, 1941, p. 453.

³ *Arch. Derm. Syph.*, Chicago, 1941, 44, 13.

⁴ *J. Amer. med. Ass.*, 1941, 117, 998.

The reaction was almost immediate and was characterized by convulsions, dyspnoea, cyanosis, coma, and death. In the cases recorded this reaction never came after the first dose, but after the second, third, and fifth. Tyson therefore believes that the reaction is anaphylactic and connected in some way with the alteration of the blood proteins in nephrosis. She believes that the use of mercurial diuretics is contraindicated in nephrosis. Here, in our opinion, she goes too far. Massive oedema is a severe handicap to a patient and a strong predisposition to infection and premature death. If there was a successful operative treatment for nephrosis we should not forgo it because of the inevitable hazards of operation. For the same reason we cannot believe that there is justification for putting a general interdict on the use of mercurial diuretics in nephrosis. Two other conclusions seem more legitimate. The first is that no practitioner should ever treat a case of nephrosis with mercurial diuretics without warning the patient's relatives of the risks entailed. The second is that restoratives such as adrenaline and nikethamide should always be at hand before the injection is given. Finally, evidence should be obtained whether similar fatalities have followed injection of the drug by the intramuscular route.

CHEMOTHERAPY FOR TUBERCULOSIS

Neither the known properties of the tubercle bacillus nor the character at least of the chronic lesions produced by it encourage the belief that the ever-widening scope of chemotherapy will come to embrace this disease. A micro-organism so slow in its growth, so impermeable by noxious agents, and producing a destructive and comparatively avascular lesion, is the very antithesis of those fully susceptible to the sulphonamides. Nevertheless the search for a chemotherapeutic agent effective in tuberculosis continues in at least two directions. A well-worn path has been pursued with characteristic German thoroughness by Prigge,¹ who tested the action of twenty-three chaulmoogra derivatives on experimental tuberculosis in guinea-pigs. One of these compounds—4-*n*-hexylresorcin-dichaulmoogroyl-ester—prolonged the life of infected animals for an average of 14.2 days, a result which is considered encouraging enough to warrant further study on these lines. A very much more striking result from experiments of the same nature is reported by W. H. Feldman and his colleagues,² who have continued their studies of promin (the sodium salt of *p,p'*-diamino-diphenyl-sulphone-*N,N'*-dextrose sulphate). It has been known since the early observations of Rich and Follis³ with sulphanilamide that compounds of this nature have some retarding effect on the development of experimental tuberculosis in the guinea-pig, but the degree of effect now described for promin is of a different order. In these experiments the animals were given a dose of 0.005 mg. of human tubercle bacilli subcutaneously, and all controls had died of the disease in 189 days. In the treated animals administration of the drug was begun either at the time of inoculation or at intervals after it varying from three days to no less than six weeks. The extraordinary feature of the results is that from the information given they appear to differ little whether treatment was begun immediately or after this long delay. At the time of death of the last control 57 of a total of 68 treated animals were still alive. Of these, 41 showed no gross signs of tuberculosis at all, including a high proportion of those in which treatment was begun after a delay of two, four, or six weeks. In the remainder the lesions were confined to the site of inoculation, or included glandular or slight

splenic involvement. These results were achieved by large doses of the drug, 300 mg. or more being consumed with food daily; this dosage caused blood changes, but no loss of weight or condition. It would be most unwise to conclude even from such results that the human disease will respond in the same way, but they are certainly more definite and encouraging than any which have gone before or than might have been expected on theoretical grounds from treatment with any such compound in this disease.

NEW VIEW ON PINK DISEASE

So long as the aetiology of pink disease remains obscure treatment of it cannot be expected to be satisfactory. Any views on the subject are therefore welcome, and what T. A. Ratcliffe has to say⁴ about a possible psychological origin must be viewed with respect, although possibly with reserve, since no alternative seems to have been generally accepted. He bases his experience on fifteen cases—six girls and nine boys—with an age of onset varying from 3½ months to 1 year and 5 months. They had all been full-time babies and all breast-fed at some time, ten of them up to the moment of admission to hospital. There did not seem to be any dietary deficiency, but, as other workers have recorded, in a high proportion some upper respiratory tract disease was associated with the onset. From the psychological aspect, Ratcliffe points out that excessive irritability is a striking symptom in most cases, and several types of mental upset are also found. In one of these the child lies in the "knee-elbow" position, crying if disturbed and showing photophobia, considered to be nothing more than a particular exhibition of irritability. In the second type there appears to be an increase of motor activity. The child is continuously crawling about its cot, or rocking itself to and fro for hours at a time. Such a child is stated to be reasonably co-operative and will "show off" to visitors. A third and rare type exhibits what is almost a catatonic state, lying for hours in strange positions in extreme lethargy. Another psychological factor to be borne in mind is the influence of the mother, and Ratcliffe states that all the mothers of the children with pink disease who were interviewed were of the "extrovert" type, with a continual cry of, "Will he be all right, doctor?" As, from experience gained in the psychological clinics for older children, this type of mother is well known to be associated with the behaviour problem child, it is argued that she may well be a factor in the production of changes in the child with pink disease. Ratcliffe asserts that the skin changes, the sensory changes, and muscular hypotonia might well be of mental origin, and that this is certainly true of the anorexia. Other changes, less easy to explain on a psychological basis, might be due to associated conditions apart from the pink disease. He argues against encephalitis as a cause of the nervous disturbances on the grounds of the complete absence of sequelae. But for a similar reason it is also difficult to accept a psychological origin, and Ratcliffe himself failed to find any history of pink disease in a small number of children seen at a child-guidance clinic. The value of this psychological theory as regards treatment would appear to lie in prevention. As a therapeutic measure Ratcliffe is an advocate of calcium lactate, administered in order to deal with the nervous irritability which is so marked in pink disease. He recommends a dose of 2½ to 5 grains three times a day, if necessary over a long period, claiming that there is an immediate improvement in appetite and sleep.

REHABILITATION SERVICES

The Minister of Health, Mr. Ernest Brown, in a speech at a luncheon given by the Corporation of Brighton during his tour of the borough's health services, spoke at some length on the Emergency Hospital Service, in particular on the arrangements for rehabilitation, defined by the Delevingne Committee in 1939 as "the restoration of the working capacity of people injured by accidents."

Mr. Brown reminded his audience that at the beginning of hostilities all countries made plans to meet large-scale air attack. The part the hospitals were assigned to play was to receive the thousands, even the hundreds of thousands, of casualties to be expected. But there was a lull until the last four months of 1940, during which four months the emergency casualty services dealt with over 80,000 patients in hospitals and first-aid posts. The lull extending over the first year of war, and the fact that even when it ended the total of casualties which the enemy had been able to inflict was less than that for which preparation had been made, enabled the Emergency Hospital Service to strengthen and extend itself. In addition to air-raid casualties and Service patients, it took in civilians who had left evacuation areas for reception or neutral areas, members of the civil defence organizations, and the Home Guard, transferred workers in industry, members of the Merchant Marine, sick and away from home, and members of the Women's Land Army.

Types of Treatment Centres

The scheme could now be fairly described no longer as a casualty scheme, but as one that tried to meet all the new war needs as they arose. Specialist treatments were developed in selected centres, to which staff and equipment were brought, and patients were transferred to one or other centre as their medical needs required. Leaving aside other specialist treatments, the Minister concentrated on the rehabilitation scheme, in which the Emergency Hospital Service had endeavoured to translate into action the main principles laid down by the Delevingne Committee. The scheme had taken shape in four types of special treatment centres:

1. Orthopaedic Centres to the number of twenty-one. These gave the most highly developed service, covering all aspects of fracture treatment from the initial resetting of the injured part through all modern stages of physiotherapy and remedial exercises to complete occupational therapy.
2. Fracture Departments (A) to the number of fifty-six, with more in preparation. These differed from the centres only in that they did not contain all the very specialized provision for certain more difficult types of case. It was far better, said Mr. Brown, from the point of view both of the patients and of making the best use of medical experts, to concentrate them in this way.
3. Fracture Departments (B) to the number of 213, mainly hospitals with facilities which in peacetime might be suitable for the second category above, but were at present unsuitable for long-stay cases owing to their vulnerable situation, though useful for short-stay and walking cases.
4. Fracture Clinics (C) to the number of 136, to fill the gaps in areas which the hospitals did not conveniently cover. Both in these clinics and at the hospitals, after discharge from the latter, a patient may within convenient reach of his home be followed up and take part in rehabilitation activities.

Restoration to Working Capacity

This organization with its 426 establishments, and more in preparation, and with eminent surgeons to advise the headquarters staff at the Ministry and the staff in every region, was the embodiment of the first and second of the Delevingne Committee's principles and part of the third. The third principle was the fullest possible restoration to working capacity, and this was bound up with labour and employment questions.

Three strands had to be brought together: the preference of the ex-patient, depending a good deal on previous occupation; the nature and degree of disablement, on which the judgment of the patient's doctor was of first importance; and the demand or opportunity in particular trades and industries. The Minister

of Labour (in his interim scheme published in October for the training and resettlement of disabled persons) had made arrangements whereby contact was made in hospital between the patient, the surgeon, and the Ministry of Labour officer. The last-named would have an interview with the patient before he left the hospital, and also with his doctor, records would be made on the basis of which the Ministry of Labour would offer advice, and when the patient had made up his mind what trade he was going into he could go to a training course. Thus the Emergency Hospital Scheme had been used to effect a transition from the pre-war situation in which the patient's treatment varied according to the initiative and resource of the local hospital to one in which the entire treatment and re-training was correlated.

Of this rehabilitation organization Mr. Brown said in conclusion: "In essentials it has come to stay. I cannot imagine that, whatever administrative arrangements may be made, we shall disperse all the medical and nursing skill that have been built up or discontinue the methods of concentrating it to the best advantage. Continuity of treatment under specialist surgeons, aggregation of special types of cases for long-stay treatment and rehabilitation will remain, and in my view so should the link with the employment machine which the Ministry of Labour has been busy forging."

These essentials of the scheme fitted in with the plans for hospital policy as a whole which the Ministry of Health recently outlined in the House of Commons.

Correspondence

The Sprue Syndrome

SIR.—I was much interested in the leader on the sprue syndrome in your issue of November 22 (p. 731), as I have just completed a paper on the same subject, which will appear in the next number of the *Guy's Hospital Reports*. My conclusions are as follows:

1. Tropical sprue, non-tropical sprue (or "idiopathic steatorrhea"), and coeliac disease are varieties of the same disorder—the "sprue syndrome"—which differ only in the part of the world in which the disorder originated and in the age of the patient.

There are three characteristic and constant features of the sprue syndrome: (1) the stools contain excess of split fat, but no excess of neutral fat, meat fibres, or starch, and no inflammatory material; (2) radiography demonstrates the disappearance of the normal feathery or herring-bone aspect of the duodenum and jejunum produced by the valvulae conniventes; (3) no pathological changes are found in the intestines after death if post-mortem changes have been prevented.

With adequate treatment normal absorption of fat is restored together with the normal radiographic appearance of the small intestine.

2. It is suggested that the characteristic features of the sprue syndrome are the result of paralysis of the muscularis mucosae, which would lead to the loss of the pumping action of the villi, by means of which fat is conveyed from the lacteal radicles of the villi into the larger lacteals, and to flattening of the valvulae conniventes without changes in the normal appearance of the mucous membrane. Paralysis of the muscularis mucosae may be secondary to loss of the normal stimulant of Meissner's (submucosal) plexus or to the effect of vitamin deficiency or some toxæmia on the plexus.

3. An exception must be made for those cases of the sprue syndrome associated with disease of the mesenteric glands: in these the hindrance to fat absorption occurs at the level of the mesenteric glands instead of in the villi.—I am, etc.,

Oxford, Nov. 27.

ARTHUR HURST.

Economy in Dressings

SIR.—The letter of my old friend Beckwith Whitehouse in your issue of November 29 (p. 787) has incited me to put pen to paper in spite of your scarcity of the latter.

Human nature being what it is, I should be gratified to know that I may have been the first to save the purchase by hospitals

of yards and yards of flannel bandage and gauze, and the nursing staff of hours and hours of measuring, cutting, and sewing, and to have decreased the discomfort of many, many patients. It is a trite saying that "there is nothing new under the sun." Probably, therefore, I cannot "lay this flattering unction to my soul," more especially since it was a hospital sister who put me wise. I was to perform a hysterectomy on this lady, who had previously undergone an abdominal operation. She begged me not to constrict her by an abdominal binder, as this was so hot and uncomfortable, especially the retaining pieces round the thighs. I agreed and went one better, stating that I would not cover the incision with any dressings.

Thus during some twenty years I dispensed with flannel binders and gauze dressings, except when a drainage tube was necessary, being satisfied with painting the incision with tincture of iodine and later with Bonney's violet-green. The patient was returned to the ward or in private to her room, clothed only in her nightgown, and her curiosity as to the position and length of the incision was satisfied after one investigation. I never remember any harm resulting. I was fortunate in my colleagues who administered the anaesthetic, since in the great majority of cases I did not have to anticipate post-anaesthetic vomiting. If by chance such occurred, or was likely to occur, an abdominal binder was put on *pro tem*.

I seem to remember the facetious remarks of my seniors, comparable to those when I first introduced indiarubber gloves and masks to my department, but the great loyalty of my immediate colleagues, so evident during a long tenure of office, was a sufficient stimulation.—I am, etc.,

London, S.W.1, Nov. 30.

COMYNS BERKELEY.

Night-blindness: A Psychological Study

SIR,—In their paper on night-blindness in recent issues of the *Journal*, Wittkower, Rodger, Scott, and Semeonoff come to the conclusion that most cases of this disorder in this country "are probably of psychological origin." They submit both negative and positive evidence in support of this contention. The former consists in their inability to detect any ocular causes for the night-blindness of their 52 subjects, and in their assumption that the soldier's diet allows of no vitamin A deficiency. As positive evidence they submit their finding of "severe psychological disorders" in the great majority, and it is presumably on this that they expect their readers to accept their conclusion.

In their account of these alleged psychological disorders the authors provide an illuminating example of what—for them—constitutes evidence, and of how easily this may be collected. As they present it, their evidence consists in "what the soldier said" and their interpretations thereof, the two being inextricably mixed as though they were of equal evidential value. In any scientific discipline this confusing of facts of observation with the deductions drawn therefrom would be inadmissible. Yet even when the reader succeeds in separating "facts" from fancies, the nature of each as presented by the authors will astonish him.

As studied by the authors, the subjects of night-blindness are said to belong to two superficially distinct personality types: an over-dependent and an ostentatiously independent type. A residue is made up of men showing both characteristics in minor degree. The over-dependent consist of men who as boys were "mummy's darlings" (at least so apparently they were found willing to confess); of men who did not play games for fear of being hurt, who had such "girlish" habits as helping their mothers about the house, and who were shy, timid, and self-conscious. This type was represented by 27 men, who are divided into four subclasses: 6 who were totally unemployable, 7 who were shiftless workers constantly losing their jobs, 11 who did moderately well in life, and 4 who even excelled. It will be noted that in this analysis the original 27 have become 28, for even arithmetic seems to have lost its character as an exact science in the authors' hands.

In the interpretation of the competent 4 men we see the beginning of those procrustean proclivities that stamp this psychological study increasingly as it proceeds, for since they were not in fact "over-dependent" their efficiency has to be dubbed "anxiety-motivated." The ostentatiously independent type is represented by 12 men whose boyhood and later life

is described as active, energetic, and masculine. As boys they were robust, stubborn and cheeky, inquisitive, leaders in games, and sports, good mixers. The third mixed group had 13 representatives, who appeared almost normal.

If we take the engagingly candid confidence of these 52 subjects at their face value, an act of faith that not everyone will be able to perform, we seem to see in them the expression—exaggerated possibly—of every type of human personality. Not so for the authors, however, for, bent on tidying up reality in the paramount interests of psychological hypothesis, they tell us that all three types are but one: for the ostentatiously independent 12 are really "soft-hearted" dependent creatures, who have over-compensated for the "inherent passive feminine trends" of which they "were vaguely aware" in themselves. The apparently normal 13 were also of this category and were simply covering up their morbid fears by trying to emulate their strong male relatives. There was no evidence of these morbid fears, but theory decides that they must have cherished them.

Thus by a free use of the notion of "over-compensation" a most satisfying—if not satisfactory—psychological harmony is introduced into this untidy human diversity. Whatever he may appear to the world the night-blind soldier is but a "mummy's darling" of a larger growth. That a few of these men had distinguished themselves in the field by gallant conduct is thus explained. They were brave simply because they were so excessively over-compensated. No man, it appears, is a hero to his psychologist.

When we come to study more closely the elements in this thesis the trail of rationalizing thinking is seen over it all. Thus, the small boy who—like most of his kind—falls off fences and trees and cuts himself in the course of his juvenile adventures is really only "helpless"; the domesticated small boy who does not scorn to help his mother is "girlish"; the small boy with a healthy inquiring mind is addicted to "prying interests and the wish to be taken notice of"; while the hollow-ness of the small boy who appears an unqualified success is revealed in his over-compensation. Thus, our night-blind soldier denied normality *a priori* becomes inevitably the victim of severe psychological disorders. It is difficult to believe that under an inquisition of this fantastic order even the keenest of night-sighted soldiers would escape intact, or with his ego untarnished, if it were deemed expedient to present him as psychoneurotic. The astonishing autobiographical reminiscences made by this collection of soldier patients leave one with the uncomfortable suspicion that some at least of them had their tongues in their cheeks, and that that incorrigible wag the British soldier was leading his naïve questioners up the garden.

On the negative side, the authors' failure to find adequate physiological causes cannot be accepted as excluding the possibility that such exist. The assumption that the soldier's diet renders a vitamin A deficiency an impossibility is a convenient one that saves the authors the trouble of ascertaining the facts. There is no such single thing as a soldier's diet, except possibly on paper.

As the matter is left by the authors, every soldier now complaining of night-blindness comes under the suspicion that he is a soft-hearted, dependent "mummy's darling." Whatever be the role of psychogenic factors in the incidence of defects of night vision, it would surely be wrong to accept the authors' thesis on no better evidence than they provide. One need not sentimentalize the soldier, who, after all, is but a sample of the population, but one cannot write him off in this cavalier fashion. The tasks of medicine are not fulfilled in this easy verbal manner, and it is to be hoped that the problem will be reinvestigated in a more balanced and scientific way by observers less swayed by psychological dogmas.—I am, etc.,

London, W., Dec. 4.

F. M. R. WALSHIE.

Testing Night Vision

SIR,—The second letter of Mr. E. W. Godding (November 29, p. 789), with his comments on the "disk-spotting test" of night vision, seems to make it plain that he has no personal experience of this particular test. He does not appear to have made any trial of its method. So that his remarks thereon are somewhat akin to the assertion in the last but one paragraph of his letter: "the 'standard candle' has not been used as the standard of

illumination since about 1900." If that statement be true, it is strange that there is still a first-class firm that makes and markets the standard sperm candle.—I am, etc.,

Edenbridge, Dec. 4.

N. BISHOP HARMAN.

X Rays in Treatment of Inflammations

SIR.—In your issue of November 15 (p. 700) there appeared an annotation on the treatment of inflammatory conditions by radiotherapy, based on an article by Pendergrass and Hodes in the *American Journal of Roentgenology*.

It would be inappropriate for us to express an opinion on the merits of this method of treatment, but we do most strongly deprecate the suggestion contained in the annotation that it could safely be carried out by casualty officers. Radiotherapy is a highly specialized branch of medicine, and requires skill, judgment, and experience in those who practise it. Proficiency in it comes only after a lengthy training, and in our opinion to allow "hospital and armaments works casualty officers" to treat these cases by x rays after having been "taught the essentials in a few weeks" would be to incur grave risk of x-ray injuries. The statistics of the medical defence societies show how real this risk is. A shortage of radiotherapists would not justify the exposure of patients to the danger of unskilled treatment. The danger is so real that it would be better not to use the method at all if no radiotherapist was available. This position has in fact not yet been reached.—We are, etc.,

S. COCHRANE SHANKS,
President.

WALTER M. LEVITT,
Vice-President and Chairman of the
Radiotherapy Section Committee

The Faculty of Radiologists,
London, W.1, Nov. 28.

M. H. JUPE,
Honorary Secretary.

SIR.—The Executive Committee of the British Association of Dermatology views with much concern the statements made in the annotation "X Rays in Treatment of Inflammations" (November 15, p. 700). While not desirous of discussing the question of the value of x-ray treatment in acute inflammations of the skin, the committee considers that the statement made in this article that there is no risk of radiation injuries in giving doses of 100 to 200 r for three to five consecutive days is not in accordance with common experience. With the apparatus generally employed for superficial therapy the doses recommended would be capable of producing severe and permanent injury to the skin.

Further, the committee considers that the recommendation made that casualty officers should be encouraged to treat their patients with x rays is dangerous to a degree. Past experience has clearly shown that this form of therapy should only be applied by those who have had long training in the use of so powerful and potentially dangerous an agent. Serious after-effects may not show themselves for many years after treatment, and without an intimate knowledge of these after-effects irreparable damage may be done to patients.—I am, on behalf of the Committee, Yours faithfully,

H. W. BARBER,

London, W.1, Dec. 1. Hon. Secretary, British Association of Dermatology.

SIR.—In the *Journal* of November 15 (p. 700) you draw attention to the recent review of Pendergrass and Hodes of the use of x-ray treatment in inflammations. Radiologists themselves are not yet agreed on the best technique for the treatment of inflammations, and your statement that "any registrar or house-surgeon who is in the habit of referring such cases to the x-ray therapy department can testify not only to the shortening of the period of incapacity but also to the restoration of useful function in fingers that would otherwise have been amputated" is a surprising one, and raises a doubt as to the value of the testimony that would be given.

Under these circumstances it is most undesirable to suggest that x rays should be used widely in the treatment of inflammations until much more research has been done in those clinics where it is possible to use accurately measured doses under conditions that can be strictly defined and repeated, and where results can be impartially recorded and controlled by comparison with patients treated by other means.

It is especially dangerous to suggest that "casualty officers could be taught the essentials in a few weeks." Some surgeons

have recently learned to their cost that x rays not controlled by competent radiologists can be dangerous, and it should be accepted that x-ray therapy should only be practised under the direction and continuous supervision of a fully experienced radiologist. I am the last to suggest that radiotherapy should only be practised by those who can do nothing else, but I do maintain that it should not be regarded as equivalent to minor surgery, but as needing as much training, care, and thoroughness as major surgery.—I am, etc.,

London, S.E.11, Dec. 1.

GEORGE F. STEBBING.

Haemoglobinometry

SIR.—Permit me to add some more practical hints to the important and interesting discussion by Dr. R. D. Campbell (November 22, p. 747) on the difficulties of everyday haemoglobinometry.

I have found by personal experience that blood kept under an atmosphere of CO will preserve its colour and CO capacity for as long as twenty-five years. I have had a Haldane tube since 1912, and it has in no way lost its accuracy and usefulness. With the Sahli apparatus, on the other hand, I have not had the same good experience. The suspension in his tube forms a sediment in time, and this cannot be redispersed even by shaking with the enclosed bead. This settling out and the discoloration give rise to inaccurate and incommensurable results. Leitz attempted to remedy these defects by using a coloured glass rod in place of the tube, but this model proved a failure.

In any case, why should one use an apparatus which gives only an arbitrary measure instead of an instrument giving absolute functional values? The chief aim of haemoglobinometry is the determination of the oxygen-carrying capacity of the blood. We know that 1 gramme of haemoglobin can absorb 1.34 c.c.m. of O₂. Sahli arbitrarily assumed that the average normal blood contains 17% of haemoglobin. He arrived at this figure by mixing together a certain quantity of blood from each of his assistants, and declaring this as the standard haemoglobin concentration in the blood of the healthy normal man and defined it as the 100% standard. This standard blood would represent an oxygen capacity of 23 vol. % O₂. Contrary to Sahli, Haldane took for his 100% standard a blood having an O₂ capacity of 18.5 vol. %. Considering, however, that Sahli's standard was the blood of persons living at Berne, 1,600 ft. above sea-level, it is obvious that his average haemoglobin concentration was considerably higher than is the average at zero altitude. Quite naturally the different values of the "100%" standard have caused some confusion, and it is not surprising that, when using Sahli's haemometer, we often find "anaemias" where in fact none exist.

Another source of error in the acid haematin method is the time of the dilution. The instruction to dilute after one minute is very vague, because after half a minute only 80% of the terminal colour reaction is reached; after one minute the change is 83%; after two minutes 88%; after five minutes 93% of the darkening of the haematin is reached. After this time the change goes on very slowly, and it takes hours for it to become complete. For this reason it is advisable to dilute the acid haematin after five minutes, when the curve of change has become less steep.

The Haldane apparatus complies with all requirements of a satisfactory haemoglobinometer, and, moreover, matches better the normal erythrocyte figures and thus gives a more accurate colour index. The difficulty of obtaining coal gas for the Haldane apparatus can be overcome by keeping a large bottle of water which is shaken with coal gas and thus becomes saturated with CO. If the water is covered with liquid paraffin this keeps the dissolved gas practically indefinitely. This water contains quite sufficient CO to convert the small samples of oxyhaemoglobin with which we deal in tests. For our daily requirements of CO water we may fill an old insulin bottle with a rubber cap from the large stock.—I am, etc.,

London, W.1, Dec. 1.

J. PLESCH.

E.N.T. Instruments

SIR.—When the E.M.S. was organized for prospective casualties from enemy action an ear, nose, and throat service was not considered an essential part of that service. As the character and functions of the E.M.S. hospitals changed and expanded to embrace all services, ear, nose, and throat work

was naturally included. It will be appreciated that in the early months of the war the "Services" had first choice of any equipment in the country, and when large numbers of special instruments for many hospitals were required a marked scarcity was revealed. The task of arranging for manufacture of those instruments was heavy and has taken many months, and, indeed, some of the orders have not yet been completed.

Ear, nose, and throat surgeons are of an ingenious turn of mind, and it is rare to find two who use the same instruments; so that disappointments are bound to be found in a standard set.—I am, etc.,

London, W.1, Dec. 3.

W. M. MOLLISON.

Endoscopic Resection of the Prostate

SIR.—Mr. W. E. M. Wardill (November 22, p. 749) has been kind enough to take notice of my description of the adjustable check method of performing endoscopic resection (October 25, p. 583). He offers three reasons for his disbelief in the efficiency of this method. I give his criticisms below, together with my replies.

1. "The necessity to make frequent references to the verumontanum as a guide to the external sphincter during the course of the operation." As I pointed out, I believe this procedure—the orientation of the entire operation around a small structure easily totally or partially obscured by slight haemorrhage—is responsible for the small but almost universal incidence of incontinence following resection. If the internal meatus-verumontanum distance is accurately measured as the initial step in the operation and therefore at a time when there is no haemorrhage, and if this distance is fixed on the resectoscope rack, it is only necessary during the operation to refer to the internal meatus, not the verumontanum. This method appears superior, as the internal meatus is a landmark far more easily identified and less easily obscured than the verumontanum; indeed, one can scarcely miss it. Further, as the cutting process starts at the internal meatus it has to be identified in either case. Mr. Wardill states that it is manifestly impossible to retain the resectoscope in a fixed position if an efficient operation is to be carried out. He has, I fear, misunderstood my remarks on this point. I said, "For obvious reasons the resectoscope sheath must be held stationary during the resection"—not during the operation. It is during the actual cutting of the prostatic strip that it is dangerous to move the resectoscope outwards the smallest degree. I have neither advocated nor attempted to practise retaining the resectoscope in a fixed position during the operation—a completely impossible achievement by any standards.

2. "Measurement by any gadget must be entirely misleading where a middle lobe exists and where the prostatic urethra varies in length from side to side." Before publishing this method I gave it a reasonable trial by removing 537 grammes from twenty-seven patients in forty-eight resections, including adenomatous, fibrous, and carcinomatous prostates. The majority of these patients had middle-lobe enlargements or variable prostatic urethras; and therefore belong to that type in which Mr. Wardill claims the use of a gadget must be entirely misleading. It is this very type that has formed the basis for its successful trial. The details of the procedure are difficult to describe but easy to perform. Suppose the right lateral lobe measures 2 cm. from the internal meatus to the verumontanum and the left lateral lobe (or middle lobe) has an intravesical projection of 1 cm. and therefore measures 3 cm. With the check set for a cutting distance of 2 cm.—that is, the shorter cutting distance—both lobes are resected. Prostatic tissue 1 cm. in length now remains from the left lateral lobe adjacent to the verumontanum. The resectoscope is held so that the loop lies at the level of the internal meatus of the right lateral lobe but facing the left lateral position (verified by rotating the instrument). The pinion is now rotated, withdrawing the loop until the remaining projecting 1 cm. of tissue comes into view (the loop will have travelled 1 cm.). The loop is engaged in this tissue, which is resected. It is impossible to resect more than this 1 cm. and therefore damage the external sphincter because the check is still set for its original cutting distance of 2 cm.

3. "It appears to me to be bad practice to cut if haemorrhage obscures the view." After the resection of some 15 grammes associated with the most careful coagulation of all

large and medium-sized spurting vessels, haemorrhage, although slight, is still sufficient to render difficult the identification of such a small structure as the verumontanum, while the identification of such an obvious landmark as the internal meatus remains easy. Further coagulation of every single oozing point in order to produce a completely clear medium is undesirable, as it leads to increased sepsis.

Occasionally a portion of the prostatic rim at the internal meatus is sharper and more prominent than the remainder (which I referred to as the prostatic ledge) and is therefore more easily identified. If this is removed last an obvious landmark is retained during the operation. I take it Mr. Wardill is referring to this point when he accuses me of the recommendation "to leave the most prominent part of the prostatic ledge at the internal meatus"—a recommendation that I never made. This, I think, is clear to anyone who reads the whole of my original sentence, of which the above few words are Mr. Wardill's incomplete and very misleading quotation.—I am, etc.,

H. T. COX.

Industry and Lactation

SIR.—In the *Journal* of November 29 (p. 783) there is a summary of the B.M.A. Report on Medical Supervision of Industrial Workers, in which the statement is made that "withdrawal from employment four weeks before confinement is usually sufficient"—on that I make no present comment—but in many cases it will be desirable for her (presumably the mother) "to remain away from work for more than four weeks afterwards." Sir, what a commentary on our civilization—which we are fighting to save! "More than four weeks." Have we jettisoned the most elementary of the rights of Man, that his mother should feed him during his first 300 days? Few are the factories where the conditions are compatible with lactation.—I am, etc.,

Holmes Chapel, Nov. 30.

LIONEL JAS. PICTON.

Publicity for Preventive Medicine

SIR.—A friend of mine is doomed to die a slow, painful death of torture to both herself and her friends and relations; she is dying from carcinoma of the cervix, which in spite of operation and x-ray therapy progresses. This patient suffered for many years from post-menopausal vaginal bleeding, of which, being a busy wife and mother, she took no notice. Had this woman realized the implication of her condition and sought medical advice earlier this tragedy might have been averted. But she did not know, and thousands of her sisters to-day do not know, just as thousands are still treating acute appendicitis with purgatives.

It is high time the medical profession abandoned its conservative attitude to this matter and made use of the facilities offered by the Press, the cinema, and the radio to educate the general public in some of the principles of preventive medicine, and not to allow the field to be monopolized any longer by the patent medicine vendors. One good talk on the radio per week would probably save thousands of lives and prevent a proportionate amount of suffering in a year. Let us use modern weapons in the fight against disease.—I am, etc.,

Food Advice for Working-class Mothers

SIR.—I hoped that an abler critic than myself would have written to comment on Mr. W. C. W. Nixon's letter (November 1, p. 633).

Any practitioner in any industrial district knows the profligate waste of good food of which the majority of working-class mothers are guilty. This gross waste is largely the result of ignorance on the part of the women, who have little or no idea of how to choose wisely or cook properly foods of the highest nutritive value. I suggest that every hospital and every maternity and child welfare clinic should have a food advice bureau with a demonstrator of cooking, similar to the one at the Soho Hospital for Women. In this way many thousands of women would learn how to avoid throwing vitamins down the sink, and make their own contribution to one of the greatest measures in preventive medicine—proper nutrition.—I am, etc.,

Bristol, Nov. 23.

N. A. MARTIN.

Control of Diphtheria in Schools

SIR.—It would be a pity if the excellent work reported by Prof. G. S. Wilson and his team of laboratory workers (*Journal*, November 29, p. 759) should give the impression among practitioners that there is a single panacea for the control of diphtheria among school children. The procedure likely to be both effective and practicable depends on such variables as the nature of the school (day or residential), its site (town or country), the stage of the outbreak (early or late), the age distribution of the children at risk, and the hospital and laboratory facilities available. To give two contrasting examples: in a residential school for older town-bred children where the outbreak has been smouldering for some weeks the incidence of carriers is likely to be high and the proportion of susceptible children low. In such a case the procedure of choice is Schick-testing followed by combined passive-active immunization of the positive reactors, without recourse to routine swabbing or isolation of carriers. On the other hand, at the onset of an epidemic in a country day-school detection and early segregation of the carriers would be most useful; but how many laboratories in the country could cope suddenly with the bacteriological examination on tellurite blood-agar plates of nose and throat swabs from 200 to 300 children? Between these extreme examples there are many gradations of circumstances, and in most instances we feel that Schick-testing is "necessary and desirable." If the small "passive" dose of antitoxin is given four to six hours after Schick-testing it will not affect the skin-response, and the restriction of active immunization to straight positive reactors lessens the risk of untoward inoculation reactions which occur most frequently among pseudo-reactors, whether Schick-positive or -negative.

The routine policy of detection and segregation of carriers raises laboratory and hospital problems, and even if hospital accommodation were available there is in England and Wales no legal power to remove carriers as such to an isolation hospital. Besides, some of them are only transient carriers whom it would be unfair to admit to a diphtheria ward. It seems to us that if the positive reactors, especially those of school and pre-school age, are given passive-active immunization and kept under medical supervision for a month, there is little point in seeking to detect and isolate carriers, whose presence in the community may help to maintain an adequate general level of immunity.

Incidentally, the noteworthy finding reported by these workers that the diphtheria bacillus was confined to the nose in more than half the carriers emphasizes what is often forgotten outside hospital practice—the prevalence of the nasal carrier and the need, where circumstances demand swabbing, for examining both nose and throat.—We are, etc.,

WILLIAM GUNN.
ROBERT CRUICKSHANK.

London, N.W.3, Dec. 6.

Obituary

T. HENRY WILSON, F.R.C.P.I.

Late King's Professor of Midwifery, Trinity College, Dublin

We regret to announce the death on November 20 in Dublin of Prof. T. Henry Wilson, formerly one of the leading obstetricians and gynaecologists of that city, who practised for many years in Merrion Square, and had been President of the Royal College of Physicians of Ireland.

Thomas Henry Wilson was born in Dublin on January 1, 1865, the elder son of Captain John Wilson of the XIV Regiment. His schooldays were passed at Trinity College, Stratford-on-Avon, and at Foyle College, Londonderry; he then entered Trinity College, Dublin, as a student of arts and graduated M.A., but did not take the medical degrees of the university. He obtained the licences of the Irish Royal Colleges in 1886 and the L.M. of the Rotunda Hospital, became M.R.C.P.I. in 1897, and F.R.C.P.I. a year later. He spent some time after qualification in postgraduate study at Leipzig.

After serving as senior master of the Rotunda Hospital Henry Wilson was appointed gynaecologist to the Richmond Hospital and to Sir Patrick Dun's Hospital, Dublin, and some years later was elected to the King's Professorship in Midwifery at Trinity College. He was for a long time examiner in gynaecology and midwifery for the Royal College of Physicians of Ireland and also external examiner in midwifery for the University of Durham and for Queen's University, Belfast. The Royal Irish Academy elected him into its membership, and for many years he took an active part in the proceedings of the Obstetrical Section of the Royal Academy of Medicine in Ireland, of which he had been honorary secretary. He held office as President of the Royal College of Physicians of Ireland in 1926-7, and had been vice-president of the Section of Gynaecology and Obstetrics at the Annual Meeting of the British Medical Association in London in 1910. He contributed several papers on gynaecological subjects to the *Transactions of the Royal Academy of Medicine in Ireland*, and on complications of labour to the *British Medical Journal*.

Prof. Wilson married in 1922 Gladys Mary, elder daughter of the late Colonel W. Lyster-Smythe of Barbavilla, Co. Westmeath. He retired from his chair in Dublin University on account of failing health.

Dr. JAMES DAVIDSON MACKAY has died at Aberdeen as the result of an injury received last May while carrying out his duties as A.R.P. medical officer in the North of England. He graduated M.B., Ch.B. of the University of Aberdeen in 1908, and after serving as house-surgeon at the Aberdeen Royal Infirmary entered the part-time public health medical service, working first as assistant in the Aberdeen Health Department, then as deputy M.O.H. to the Kincardine County Council. Later he was appointed M.O.H. for the Borough and Rural District of Bridport, the Borough of Lyme Regis, and the Rural District of Beaminstor. He joined the British Medical Association in 1910 and took the D.P.H. in 1932.

Dr. ALGERNON EDWARD LUXE WEAR, for over thirty years chief medical officer to the Leeds Education Committee, died on November 30 at his home in Harrogate. He was born at Newcastle-upon-Tyne in June, 1866, and was educated at the Newcastle Royal Grammar School, at Durham University, and at University College, London, graduating M.B., B.S. in 1891, M.D. three years later, and taking the D.P.H. in 1912. He held resident posts in Leeds and was appointed school medical officer for the city in 1910. Dr. Wear was an old volunteer, and on the formation of the Territorial Force in 1908 became lieutenant-colonel, 1st West Riding R.A.M.C. He went to France on the outbreak of the last war as commanding officer of No. 7 Casualty Clearing Station, was mentioned in dispatches, awarded the C.M.G. in 1915, and promoted to the rank of Colonel A.M.S. He had been a member of the British Medical Association for thirty years, and was a past president of the Yorkshire Branch of the Society of Medical Officers of Health.

We regret to announce the death on December 1 of Mr. FREDERICK NESFIELD COOKSON, F.R.C.S., at the Staffordshire General Infirmary, which he had served long and faithfully as surgeon and afterwards as consulting surgeon. He was born in 1871 and studied medicine at the Middlesex Hospital, where he won the Freer-Lucas Scholarship and acted as house-surgeon after graduating M.B. of the University of London in 1894. He held the posts of clinical assistant at the Chelsea Hospital for Women and house-surgeon at the Bristol General Hospital, and proceeded to the M.D. degree in 1898, taking the Fellowship of the Royal College of Surgeons in 1899. Mr. Cookson was a member of the British Medical Association throughout his career at Stafford, and his local colleagues nominated him to serve as representative of the Division on three occasions—in 1906 in London before the Annual Meeting held that year at Toronto, in 1908 at Sheffield, and in 1909 at Belfast. He retired from active work a year or two ago.

One of the many directions in which South African money gifts to this country are being used is to provide a weekly meeting for women and children undergoing hospital treatment for air-raid burns which have caused bad disfigurement.

The Services

HONORARY SURGEON TO THE KING

Major-General R. E. Barnsley, M.C., late R.A.M.C., has been appointed Honorary Surgeon to the King, in succession to Major-General W. B. Purdon, D.S.O., O.B.E., M.C., late R.A.M.C., who has retired.

NAVAL AWARD AND MENTION IN DISPATCHES

The D.S.C. has been awarded to Temporary Surgeon Lieut. Benjamin Crawshaw, R.N.V.R., for bravery and devotion to duty when H.M.S. *Grimsby* was lost.

Surgeon Lieut. Charles John Roberts, R.N., has been mentioned in dispatches for bravery and devotion to duty when H.M.S. *Auckland* was lost.

EFFICIENCY DECORATION, TERRITORIAL ARMY

The Efficiency Decoration of the Territorial Army has been conferred on Lieut.-Colonel Ranfurly Percival Stanley Kelman and Major Alfred Badenoch, R.A.M.C.(T.A.).

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

Wounded

War Substantive Captain William Robert Gemmell.

Universities and Colleges

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

The examiners have satisfied the examiners at the exam.

M.B., B.Ch.—*Obstetrics and Gynaecology*: H. J. Houghton, Dorothy M. Hyde, Tessie Phillips, Annie M. Rees, Dilys M. Rees, Dorothy Roberts, D. G. H. Tutton, A. K. Toufeeq, S. E. Williams. *Surgery*: Beryl Bevan, W. M. Jones, Monica Parry-Morton. *Pathology and Bacteriology*: E. R. Edmunds, Phoebe J. M. Griffiths, T. Jones, H. D. Walters, A. A. Yauniskis.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—J. H. Ebbetts, M. C. Hannon, C. H. Kitchen.

MEDICINE, PATHOLOGY, AND FORENSIC MEDICINE.—C. Farès, R. Gunewardena, J. T. Hemingway, C. H. Kitchen, F. G. Leekam, S. A. MacDonald.

MIDWIFERY.—S. E. Gordon, R. J. C. Hutchinson, H. G. King, S. A. MacDonald, R. Mather, N. Rao, C. J. O. Taylor.

The diploma of the Society has been granted to M. C. Hannon and F. G. Leekam.

FACULTY OF RADIOLOGISTS

The following candidates have satisfied the Fellowship Board at the examination for the Fellowship of the Faculty: *Radio-diagnosis*.—Eric Samuel, M.D., F.R.C.S., D.M.R.E. *Radio-therapy*.—Alice Margaret Ross, M.B., Ch.B., F.R.C.S.Ed., D.M.R.E.

Medical Notes in Parliament

Conscription of Women

In the House of Commons on December 2 Mr. CHURCHILL moved a resolution stating that, in the opinion of the House, for the purpose of securing the maximum national effort in the conduct of the war and in production, the obligation for National Service should be extended to include the resources of woman-power and man-power still available, and that the necessary legislation should be brought in forthwith.

Explaining the new proposals, the Prime Minister said that there would be three important changes in the case of males. Hitherto reservation from military service had been by occupational blocks. It was now proposed to change over gradually from this system to that of individual deferment. The sole test would be the importance to the war effort of the work on

which the man was engaged. It was proposed to raise the age of reservation by one-year steps at monthly intervals, beginning on January 1, 1942. The age for compulsory military service would be raised from 41 to 51. Men called up over 41 would not be posted for the more active duties with the Forces. It was not intended to call on anybody to do tasks for which he was physically unfitted. It was proposed to lower the age of military service to 18½, and to register boys and girls between the ages of 16 and 18.

It was not proposed at present to extend compulsion to join the Services to any married woman, though they could, of course, volunteer. The existing power to direct married women into industry would continue to be used with discretion. It was proposed to take powers to require women to serve in the uniformed auxiliary Forces of the Crown or Civil Defence. All those affected would have exactly the same rights and safeguards as men subject to compulsory service. The new power would be applied in the first instance, and probably for some time to come, only to unmarried women between 20 and 30. This special movement of young women must be directed to the A.T.S. It was not proposed, when once they had joined the A.T.S., to compel them to serve in the lethal or combatant branches. Women would have the right to volunteer, but no woman in the A.T.S. would be compelled to go to the batteries.

In the great field of married women and women doing necessary household work, comprising about 11,000,000 persons, the Government saw their largest reserves for industry and home defence in the future. The part-time employment of women in industry had already been developed, but on nothing like the scale which must be reached in the months before us. To this matter employers would be wise to give their immediate attention, to see how they could adapt their businesses. There was an immense variety of arrangements to enable women to divide up domestic tasks and be free to work close at hand in the factory or the field. In some cases women would arrange to "Box and Cox," in others a group of five or more might arrange for each to cook a day in turn, or, again, the development of crèches and public nurseries or combined nurseries might free or partially free mothers of families from domestic duties. Wherever practicable work would be brought as near to the homes as possible.

Mrs. TATE said that there was a deplorable degree of absenteeism in the factories, and it was greater among women than men. One of the main reasons for the absenteeism of women was the inadequate number of nursery schools and day nurseries in which women could leave their children while they worked in the factories.

On December 4, after three days' debate, the House of Commons carried by 326 to 10 a motion declaring that the obligation for National Service should be extended to include the resources of woman-power and man-power still available. Replying to the debate Mr. BEVIN said it had been arranged that women doctors would serve on medical boards to take care of the women called up. The proposed registration of boys and girls at 16 was the first beginning in dealing with the adolescent in an organized manner. After the division Mr. Bevin introduced the National Service Bill, and it was read a first time.

Alleged Incorrect Medical Certification

In a reply on December 4 to Captain C. S. Taylor, Mr. BEVIN said that last year the police investigated a number of cases in which members of the medical profession were alleged to have provided incorrect medical certificates for men of military age, stating that they were unfit for military service. The evidence was not sufficient for a prosecution. Further cases were under investigation. He could not say whether particulars of these cases had been reported to the General Medical Council. He assured Sir Henry Morris-Jones that, in the interests of the medical profession, he would adopt ruthless measures in the case of anyone found guilty. Mr. Bevin added: "I have to get evidence before I can bring a prosecution. Doctors are very fortunate; they can bury their mistakes."

Captain TAYLOR gave notice that he intended to raise this matter on a subsequent day on the motion for the adjournment of the House.

No. 47

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 22.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

EPIDEMIOLOGICAL NOTES

Discussion of Table

The chief features of the returns for England and Wales for the week were the increased incidence of pneumonia, 103 cases, and scarlet fever, 65 cases, and the decline (71) in the notifications of whooping-cough. The rise in the pneumonia figures was contributed by the West Midlands, North Midlands, and North-Western Counties. The weekly number of cases from this disease has been doubled since the week ending November 1. The rise in the incidence of scarlet fever was confined to Wales and the South-Western and North-Western Counties: the notifications reached the largest weekly total recorded this year. Although the notifications of whooping-cough declined for the country as a whole, two counties showed substantial rises: Lancashire had an excess of 40 cases compared with the preceding week, due to the experience of the county boroughs; London had an increase of 33 cases, the largest returns for the metropolitan boroughs being those of Islington 23, Lambeth 20, and Wandsworth 25.

In Scotland the number of cases of diphtheria reported, which was 324 and an increase of 62 on the preceding week, reached a new high level. The increase was due mainly to the western area, where 253 cases were notified against 193 in the previous week.

Dysentery

Although the notifications of dysentery in England and Wales exceeded those of the preceding week by only 5, the total was the largest recorded for three and a half years, over one-third being contributed by two counties—Surrey 42 and Lancashire 34. The largest of the new outbreaks were in Bedfordshire, Biggleswade R.D. 25; Hertfordshire, Berkhamsted U.D. 14 and St. Albans R.D. 4; Shropshire, Ellesmere R.D. 20.

In Scotland there was an increase of 21 cases. Glasgow, where notifications rose from 4 to 21, was the only area in which they differed appreciably from the preceding week.

Paratyphoid and Typhoid Fevers

For the twelfth consecutive week a drop in the number of notifications has been recorded in England and Wales, and the incidence now tends to the usual endemic level. A relatively large number of notifications, arising from local outbreaks of paratyphoid, has been the feature of the returns during the summer and early autumn. During the six months beginning May 18 the number of cases notified was 4,066, as compared with 1,039 and 727 for the corresponding periods of 1939 and 1938 (when paratyphoid and typhoid were still notified together under "enteric fever"). The various outbreaks were due to infected food, and the largest of these local epidemics of paratyphoid were those in the districts of Liverpool and Bristol. The former, which originated in a multiple bakery, spread through the surrounding districts, and 883 cases were notified between June 7 and September 13, 530 of them in Liverpool. In Bristol 195 cases were notified during the four weeks from August 17 to September 13. The outbreaks have been generally of a mild type, and in the 126 large towns, for which the number of deaths is available, the ratio of deaths to cases during the present year was 1 to 34, compared with the rate of 1 to 22 in 1940.

Quarterly Returns for Eire

The returns of the Registrar-General for the third quarter of 1941 have been issued. The birth rate was 20.1 per 1,000, 0.7 above the rate for the third quarter of 1940. Infant mortality was 64 per 1,000 births, as compared with 50 for the corresponding period of 1940. A death rate from puerperal causes of 2.7 per 1,000 births was recorded, 0.2 below the rate for the September quarter of last year. The general death rate was 11.6 per 1,000, being 0.1 in excess of the third quarter of the preceding year. Of the 317 deaths from diarrhoea and enteritis under the age of 2 years, 223 were recorded in the city of Dublin.

Returns for the Week Ending November 29

The number of notifications during the week in England and Wales included scarlet fever 1,415, whooping-cough 1,959, diphtheria 1,047, measles 850, pneumonia 1,101, cerebrospinal fever 140, poliomyelitis 15, dysentery 197, paratyphoid 16, and typhoid 7. Thirty-seven deaths were due to influenza.

Medical News

Colonel H. Letheby Tidy will deliver a lecture on "Non-tuberculous Infections of the Chest" at the Weston Hotel, Bath, on Thursday, December 18, at 5.30 p.m. All Service medical officers and civilian practitioners will be welcome.

The next annual general meeting of the British Orthopaedic Association will take place in Oxford on January 2 and 3, 1942. The scientific sessions will be held in the lecture theatre of the Department of Human Anatomy at 9.30 a.m. on both days. The programme includes an address by the president, Prof. T. P. McMurray, on "Conservatism in Orthopaedic Surgery," and a paper by Prof. Philip Wilson (New York) on "Arthroplasty."

The first training course for industrial accident prevention organizers ever held in this country, arranged by the Royal Society for the Prevention of Accidents on behalf of the Factory Department of the Ministry of Labour and National Service, was such an outstanding success that a second course will be held at Balliol College, Oxford, from January 2 to 13. Programme and syllabus may be had from "Rospa," 52, Grosvenor Gardens, London, S.W.1, or 426, Strand, Cheltenham, Glos.

Scotland is brought into line with England and Wales by an Order which the Secretary of State has issued limiting the proportion of liquid paraffin in emulsions. On and after December 15 it will be illegal for an emulsion to be manufactured containing more than 25% volume in volume of liquid paraffin. The new Order—Paraffin Emulsion (Reduction of Liquid Paraffin) (Scotland) Order, 1941, issued under Regulation 55 of the Defence (General) Regulations, 1939—deals with manufacture, but still leaves a doctor free to prescribe for the requirements of individual cases.

The first specimen of radium in Spain has been found in Cordoba and has been given to the Spanish Cancer Institute.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles should communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

QUERIES AND ANSWERS

X-ray Therapy in Peptic Ulcer

Dr. CHARLES HORWITZ (London, N.1) writes: I have been wondering if it would not be possible for our x-ray specialists to work out some formula for the treatment of peptic ulcer by means of carefully graduated doses of x rays. The healing and curative properties of carefully controlled and graduated doses of x rays in selected cases in other conditions are now well established, but I do not recall having read or heard of any experiments in this connexion. The present medical treatment of peptic ulcer is long and tedious and unsatisfactory in many cases, and entails an exacting regimen for the patient. It might well prove that a combined treatment of rest, diet, alkalis, and a course of graduated doses of x rays might materially shorten the time required to bring about the healing of these ulcers of the stomach.

Stabbing Heel Pains

Dr. J. BUCHANAN (Killyclogher, Omagh) writes: In answer to W. R. S. (November 15, p. 716) it seems possible that the pain may be caused by senile arteriosclerosis in the leg and foot. The details given are too few for a definite diagnosis. My reasons for

forming this opinion are: (1) It comes on at "night." (2) It seems to be a "rest" pain, coming on when the patient is still and quiet. (3) It comes when the patient is in the horizontal position, and not when the leg is dependent. (4) It seems to come on in the heel (or sole) without any obvious "cause." The presence or absence of obstructed arteries, paraesthesia, or claudication, etc., should be considered. Prof. Learmonth of Edinburgh (in the *Practitioner*, March, 1939, p. 247) says Dr. Buerger's exercises are of definite value: (a) leg up, 60 degrees, (b) leg down, (c) leg horizontal; change every two or three minutes; one hour three daily.

Income Tax

Repairing Lease

"EPSILON" inquires whether, if he hires a house on a full repairing lease for ten years, he can have a deduction for so much of his expenditure on repairs as is not set against his professional earnings.

** The relief for maintenance of property is given to the owner, and "Epsilon" can therefore claim the residue only to the extent to which he has to pay tax as the owner of some beneficial interest in the property. If, for instance, the rent is, say, £100, and the net assessment under Schedule A is, say, £120, he can claim against the £20 (£120-£100) which represents amount of his interest in the yearly income from the property.

Two Cars Maintained—Obsolescence

J. F. has kept two cars for his work for about twenty years and has always been allowed obsolescence on both. This year the local inspector of taxes takes the view that owing to the decrease of income he can only allow it on one car. J. F. proposes to appeal.

** We cannot see the justification for the inspector's attitude. Rule 6 relating to Cases I and II, Schedule D—which is the relevant provision—refers to "machinery or plant used for the purposes of the trade" [or profession], and the inspector has no right to object on the ground that more plant and machinery is in fact used than he or some other persons may think is economical or necessary.

Removal to Another Practice

T. M. sold his practice in the North of England and bought a practice in the South. Can he deduct the cost of removal?

** In our opinion—No. In a case decided in 1905 (*Granite Supply Association v. Kitton*) it was held that the expense of removing a business from one place to another was inadmissible; it seems to follow, *a fortiori*, that an expense incurred in relinquishing one business (or practice) and removing to another would also be inadmissible.

Construction of Air-raid Shelter

J. D. has had an air-raid shelter constructed at his residence so that he "can be available to patients in cases of emergency." The inspector of taxes has refused to allow a deduction for a proportion of the cost.

** We understand that some allowance is given where the protection takes the form of strengthening but not altering the structure—for example, by strutting with steel or timber, bricking-up windows, etc.—but is refused where the protection takes the form of some additional structure. The ground of distinction is that, whatever be the position as regards expenditure of the former kind, the latter is clearly capital outlay. There seems to be adequate legal ground for that view.

LETTERS, NOTES, ETC.

Scabies

Dr. W. J. YOUNG (Harston, Cambridge) writes: Much is written in the *Journal* about the use of sulphur in this trouble. I should like to point out that whereas one and all advocate the use of sublimed (flowers of) sulphur, the precipitated sulphur is much more active. I notice, too, in the recent correspondence no mention has been made of Vlemingck's solution, a solution of sulphides of calcium, which was almost universally used fifty years ago.

Confusion of Names

Dr. A. TANDY CANNON writes: Certain newspapers published reports relating to the recent appearance of Dr. Alexander Cannon before the General Medical Council, and due to the fact that his registered address is shown as 38, Harley Street, proceeded to describe him as "a Harley Street psychiatrist." Apparently, however, this is not his present address, and it would seem that I am the only psychiatrist of that name now practising in this area. In view of the above circumstances certain persons have been led to believe that I am the Dr. Cannon referred to, and I would therefore be grateful if you would publish this letter, as of course I have no connexion with the Dr. Cannon in question and I am in no wise related to him.

DUODENAL INTUBATION

SIGNIFICANCE OF THE CELLULAR CONTENTS OF BILE IN THE DIAGNOSIS OF DISEASES OF THE BILIARY TRACT

BY

A. FIDLER, M.D.

JAMES INNES, M.B., Ch.B., M.R.C.P.Ed.

AND

L. S. P. DAVIDSON, B.A., M.D., F.R.C.P., F.R.C.P.Ed.

(From the Department of Medicine, Edinburgh University)

In cases of suspected disease of the biliary tract three methods of investigation are available. The first is a thorough clinical examination, the second the radiological investigation of the biliary tract, and the third the examination of the bile obtained by duodenal intubation after the use of magnesium sulphate or some other biliary stimulant. The bile is then submitted to cytological, bacteriological, and chemical examination, reliance being placed mainly on the former, since the most important diagnostic criterion is held to be the presence of cells and flocculi in the bile. It is with this particular aspect that this communication is mainly concerned.

The method of duodenal intubation was introduced into clinical medicine by Lyon in 1923. The underlying basis of the test was the observation by Meltzer in 1917 that the entrance of magnesium sulphate into the duodenum caused a relaxation of the sphincter of Oddi. Following the publication of Lyon's monograph the test was widely used throughout the world, though probably to a greater extent in America and on the Continent than in Great Britain. Although reference to the method is still found in many standard works dealing with diseases of the biliary tract, improvements in the technique of cholecystography have resulted in the test being less frequently carried out than formerly. Nevertheless in some clinics duodenal intubation is still retained as part of the full investigation for all types of disease of the biliary tract. In Great Britain, however, it is held to be of particular value for the diagnosis of simple catarrhal cholecystitis in which structural changes in the gall-bladder wall have not developed to such a degree as to be demonstrable by radiology. As recently as 1937 McNee, writing on catarrhal cholecystitis, states that it cannot be diagnosed by simple clinical methods or by cholecystography, and that "duodenal intubation is at present the only diagnostic method on which we can positively rely. It is too little used in Britain, but is a routine method in America and elsewhere."

During an investigation into the possible value of sulphonamide drugs as biliary antiseptics we noticed that many cells were present in the bile recovered when magnesium sulphate was used as a biliary stimulant, whereas cells were absent in the same patients when certain other stimulants were employed. This observation suggested that magnesium sulphate might have produced the cells by irritation of the mucous membrane of the duodenum and

that in consequence their presence did not necessarily indicate pre-existing inflammation in the biliary tract. To test this hypothesis we thought it necessary to carry out the following procedures:

1. Intubation of cases with no clinical evidence of biliary or gastro-intestinal disorder, using magnesium sulphate as the stimulant. The cases in this group would act as a control series, since for the purposes of this investigation these patients may be considered as normal persons. The finding of cells in the bile would suggest that the magnesium sulphate was acting as a local irritant.
2. Intubation of the same cases, using as stimulants substances which appeared unaltered in the duodenum in the course of normal digestion, such as peptone or olive oil. The absence of cells in the bile after the use of these physiological stimulants, under exactly similar circumstances and in the same cases, would suggest a local irritant action of the magnesium sulphate.
3. Intubation, prior to operation, of patients with disease of the biliary tract, and examination of the bile aspirated at operation from the gall-bladder and, where possible, from the common duct.
4. Observation of the effects of a similar solution of magnesium sulphate on the mucosa of different parts of the human gastro-intestinal tract exposed at operation, or in fistulae.

Methods

The tube was introduced into the stomach and the contents were evacuated. The patient was then made to lie on the right side with the pelvis elevated on pillows. Usually within one hour the first sample of bile, so-called Bile A, appeared and was collected. One of three stimulants was then injected through the tube. These were 30 c.cm. of 33% magnesium sulphate, 30 c.cm. of 10% peptone, and 30 c.cm. of olive oil warmed to body temperature before injection. Lyon (1923) recommended the introduction of 75 c.cm. of a 33% solution of magnesium sulphate, but since 30 c.cm. of a 33% solution has been found by ourselves and others to produce a good biliary reflex and to yield a free flow of dark bile (Bile B), we are satisfied that the smaller quantity is adequate. After injection, 20 c.cm. of air was blown through the tube to ensure that all the stimulant reached the duodenum, and then the tube was clipped for three minutes to prevent reflux. After this the bile was allowed to flow freely into test-tubes.

Where possible, intubation was performed in each patient on three occasions, but in some cases only one or two

examinations could be undertaken. Nearly all the patients were intubated at intervals of two days, a different stimulant being employed on each occasion, but in five cases magnesium sulphate was used immediately after the reaction following peptone had finished.

We considered as Bile B (so-called gall-bladder bile) the dark bile, which was collected until its colour returned to that seen before the stimulant was introduced. In the few cases in which this dark bile did not appear, the bile collected within forty-five to sixty minutes after injection of the stimulant was called Bile B.

Estimations of the bilirubin and protein content of the various samples of bile were made, but as the results do not affect the subject of the present report they are not given here.

Where flocculi suspended in the bile were visible to the naked eye they were removed by pipette for examination. Where flocculi were absent the bile was centrifuged and the deposit examined microscopically. Whereas the cells in the bile can be easily seen in the deposit of fresh specimens, considerable difficulty was experienced in staining them. We note that Lyon and most other workers report only on such unstained material. Attention is drawn to the fact that digestion of the cellular elements in bile takes place rapidly on standing, hence the need for early examination of the deposit.

Through the courtesy of Prof. J. R. Learmonth the opportunity was taken of observing the direct action of magnesium sulphate on the mucosa of the human stomach, duodenum, jejunum, and ileum exposed during the course of various surgical procedures. A small glass cylinder containing the test solution of magnesium sulphate was placed on the mucosa, and samples were removed at intervals of three, five, eight, and ten minutes. Controls with saline or peptone were first carried out.

Material

Duodenal intubation was performed on 33 subjects. Of these, 21 were chosen as control cases because they suffered from no disease of the gastro-duodenal or biliary tract, while 12 were proved cases of chronic cholecystitis with cholelithiasis. Of this latter group 8 were submitted to cholecystectomy subsequent to duodenal intubation. In all, 68 intubations were performed. Details of the

0 = Clear bile. No flocculi seen. Centrifuged deposit shows no cells, or only a very few small flecks of mucus containing small groups of cells.
 + = Clear bile. No flocculi seen. Centrifuged deposit contains moderate number of cells occurring in groups with mucus.
 ++ = Flocculi seen in small numbers.
 +++ = Flocculi seen in large numbers.
 Flocculi vary in size from a pin-head to a match-head, and consist of a mass of round cells bound together by mucus. Each flocculus usually contains very large numbers of cells.

(a) = Gall-bladder full of stones with no bile.

(b) = Bile contaminated with blood from operative trauma.

(c) = Gall-bladder full of stones, with no bile.

(d) = A few R.B.C.s only.

(e) = A few columnar epithelial cells not seen in previous medical drainage.

Symbols indicating number of cells as in Table I.

biliary stimulants employed and the results obtained are shown in Tables I and II. In the 8 cases in which operation was performed bile was aspirated from the gall-bladder, and in 4 of them it was possible to obtain bile from the common duct as well. The direct effect of a solution of magnesium sulphate on the human alimentary mucosa exposed at operation was observed in 5 patients, seven tests being carried out.

Results

1. *Cytology of the Bile obtained by Duodenal Intubation Before the Use of Biliary Stimulants.*—Cells were usually absent from the centrifuged deposit of Bile A of all patients, though in a few cases occasional flecks of mucus containing small groups of cells were seen.

2. *Cytology of the Bile obtained by Duodenal Intubation in Normal Cases After the Use of Biliary Stimulants.*—From Table I the following results may be summarized:

Of 19 cases in which bile was obtained after magnesium sulphate 12 showed numerous flocculi containing large numbers of cells, 5 showed no flocculi but the centrifuged deposit contained a moderate number of cells occurring in groups with mucus, and in the other 2 cases no flocculi and only very scanty cells were found on centrifuging.

Of 17 cases in which bile was obtained after peptone 14 showed no flocculi and only very scanty cells in the centrifuged deposit, while 2 cases had no flocculi but a moderate number of cells in the centrifuged deposit.

In all 8 cases in which bile was obtained after olive oil no flocculi were seen, and only very scanty cells were found in the centrifuged deposit.

3. *Cytology of the Bile obtained by Duodenal Intubation in Cases of Chronic Cholecystitis and Cholelithiasis After the Use of Biliary Stimulants.*—From Table II, A, the following results may be summarized:

(a) *Cases not submitted to Operation (Cases 1 to 4).*—In 2 cases out of 3 (Cases 1, 2, and 4) of cholecystitis and cholelithiasis in which magnesium sulphate was used as a biliary stimulant numerous flocculi containing many cells were found. In all 4 cases (Cases 1 to 4) in which peptone was used, and in Case 1, in which olive oil was employed, no flocculi were seen and only very scanty cells were found in the centrifuged deposit.

(b) *Cases submitted to Operation (Cases 5 to 12).*—In the 6 cases (Cases 5, 7, 9, 10, 11, and 12) in which magnesium sulphate was used as a biliary stimulant before operation numerous flocculi containing a large number of cells were found. In only 1 case out of 6 of this group in which peptone was used were there a moderate number of cells in the centrifuged deposit.

In the 2 cases (Cases 5 and 6) in which olive oil was employed only very scanty cells were seen in the centrifuged deposit.

4. *Cytology of Bile aspirated at Operation from the Gall-bladder or Common Duct of Patients in Group 3 (b).*—From Table II, B, the following results may be summarized:

In 5 cases of cholecystitis and cholelithiasis (Cases 6, 8, 9, 11, and 12) confirmed at operation and by subsequent pathological examination of the gall-bladder no cells were found in the bile aspirated directly from the gall-bladder at operation. In Case 10 only a few columnar epithelial cells were present in the gall-bladder bile, such cells not having been recovered previously by medical duodenal drainage. The failure to obtain bile from the gall-bladder in two cases (Cases 5 and 7) at operation was attributable to the fact that it was completely filled with calculi.

Common-duct bile was obtained from 4 cases (Cases 5, 6, 10, and 12) of this same group. In two of these (Cases 5 and 12) no cells were found in the bile; in Case 6 there was contamination with blood but no excess of leucocytes or epithelial

MORPHOLOGY OF CELLS IN THE BILE REMOVED BY DUODENAL INTUBATION

In all cases an attempt was made to establish the nature of the cells observed in the bile. In the fresh preparations

FIG. 2.—Cells as in Fig. 1 stained with Leishman, simulating polymorph leucocytes. ($\times 400$.)

FIG. 3.—High-power photomicrograph of cells as in Fig. 2, showing that the cells which appear to be polymorph leucocytes are in reality epithelial cells with disintegrating nuclei. ($\times 1,000$.)

FIG. 1.—Photomicrograph of wet preparation of cells in flocculi in bile obtained by duodenal drainage after the use of 50 c.c.m. of 33% magnesium sulphate. ($\times 400$.)

cells; and in Case 10 only a few columnar epithelial cells were present, though these had not been found on previous medical biliary drainage.

It is of interest to note that in Cases 5, 9, 11, and 12 no cells were present in the bile aspirated from either the gall-bladder or the common duct, whereas large numbers of cells were found in the bile obtained by duodenal intubation after magnesium sulphate.

5. *Effect of Magnesium Sulphate on the Human Alimentary Mucosa exposed at Operation.*—In the 5 cases in which the investigation was made it was noted that a marked congestion of the mucous membrane with exudation of red blood cells occurred after a few minutes' exposure to magnesium sulphate, whereas normal saline and peptone solution had no such effect. In one experiment involving a portion of ileal mucosa of a patient, samples studied after three, five, and eight minutes contained an increasing number of cells similar in appearance to those recovered from the duodenum by intubation after magnesium sulphate.

the vast majority of cells appeared to be round cells (Fig. 1), and only a very small number were recognizable as columnar epithelial cells. The round cells were approxi-

mately the same size as leucocytes, and to begin with we considered them to be leucocytes. This first impression received support from examination of the deposit stained with methylene blue, neutral red, and Leishman, as many of the nuclei appeared to be lobulated. The stained preparations were, however, far from satisfactory, and accordingly we decided that it was necessary to remove the cells from the influence of bile, digestive juices, and hypertonic magnesium sulphate solution by washing the flocculi immediately in saline and then suspending them in serum. A considerable improvement in staining effects was thus obtained, which enables us to say with confidence that the vast majority of round cells seen in the wet preparations were in reality cuboidal epithelial cells whose cytoplasm had largely disappeared and whose nuclear chromatin was rapidly undergoing degenerative changes (Figs. 2 and 3). Examination under the oil-immersion lens clearly reveals the difference between the detached broken-up portions of nuclear chromatin and the lobulated nucleus of a leucocyte. Bile-stained cells were noted in about 40% of our cases. The occurrence of fatty acids and salts in the deposit of bile obtained after olive oil must be remembered, as they may be mistaken for cellular elements.

Summary of Results

1. Bile removed from normal persons by duodenal intubation before the administration of biliary stimulants contained a negligible number of cells.

2. Bile removed from normal persons after the administration of magnesium sulphate usually contained many cells; whereas bile removed from the same patients after the administration of peptone or olive oil contained a negligible number of cells.

3. Bile removed by duodenal intubation from cases of chronic cholecystitis and cholelithiasis, following the administration of magnesium sulphate, usually contained many cells, whereas after other biliary stimulants cells were absent or scanty; furthermore, bile aspirated from the gall-bladder and common bile duct of the same patients at subsequent operation contained a negligible number of cells.

4. The irritant effect of a concentrated solution of magnesium sulphate on the human alimentary mucosa exposed at operation was demonstrated.

It can be concluded from the above experiments that bile removed by duodenal intubation, following the administration through the tube of 30 c.cm. of a 33% solution of magnesium sulphate, may contain large numbers of cells produced by the local irritation of this concentrated solution on the duodenal mucous membrane.

Discussion

It is not the primary object of this communication to evaluate the Meltzer-Lyon test in the diagnosis of disease of the biliary tract. Its purpose is to draw attention to a finding not previously recorded so far as we are aware—namely, that magnesium sulphate can cause desquamation of duodenal epithelial cells in large numbers and that a real danger exists of mistaking such degenerating cells for pus cells, as will be clearly realized from a study of the photomicrographs depicted in Figs. 2 and 3. We do not deny that pus cells and columnar epithelial cells may appear in the bile obtained after the introduction of a biliary stimulant in cases of acute or subacute inflammatory conditions of the biliary tract. We do suggest, however, that a concentrated solution of magnesium sulphate is not a suitable stimulant for use in the Meltzer-Lyon diagnostic

test, because the interpretation of the cytological findings in the bile is complicated by the presence of cells produced locally in the duodenum. It would appear that 30 c.cm. of a 10% solution of peptone would be a satisfactory non-irritating biliary stimulant to employ.

The reasons for our belief that the duodenal mucosa is the source of the cells present in the bile obtained after the administration of magnesium sulphate are based on the experiments and cytological studies already described. In addition it should be noted that the appearance of the cells shown in Fig. 1 would seem to be identical with the cells shown in photographs 23 and 25 in Lyon's *Atlas of Biliary Drainage Microscopy* (1935), which are stated to be cuboidal duodenal cells obtained by intubation of a case of duodenitis. No mention is made by Lyon of the possibility that magnesium sulphate might itself give rise to a duodenitis with a consequent desquamation of epithelial cells.

Lyon states (1923, p. 319): "In all normal gall tracts all three of these different-coloured bile fractions (A, B, and C) should be perfectly clear and transparent and contain no microscopical cytology in the uncentrifuged specimen." He also writes that the first criterion as regards diseases of the biliary tract is "furnished by the gross observation of the amount of floccules which can be seen in uncentrifuged specimens. If these criteria are accepted, then the majority of our control cases were suffering from disease of the biliary tract."

Lyon also lays stress on the type of cells in the specimens of bile as indications of the site and degree of inflammation. Thus he holds that columnar epithelial cells alone are indicative of catarrh of the superficial layers of the mucosa of the biliary tract and are associated with leucocytes when the deeper layers are affected. Moreover, he maintains that the cells must be bile-stained before their origin from the biliary tract can be accepted, although he admits that if there is dysfunction of the sphincter of Oddi desquamated epithelial cells and pus cells from the stomach and duodenum may be bile-stained. If these criteria are accepted, then in the majority of our cases the flocculi observed in Bile B and Bile C (flowing after Bile B and lighter in colour), which contained large numbers of round cells unstained with bile, could not have come from the biliary tract.

The absence of flocculi and cells in the yellow Bile A obtained before the administration of magnesium sulphate and their presence in the dark Bile B (gall-bladder bile) after the administration of magnesium sulphate naturally suggest that the site of derivation of the cells must be the gall-bladder or the bile ducts. We believe that this assumption is not necessarily justified, because similar results would occur if the time required for the development of the irritant action of magnesium sulphate on the duodenal mucosa coincided with the time needed to cause a relaxation of the sphincter of Oddi. In our experience this is precisely what happens in most cases. In some instances, however, duodenal irritation develops rapidly, and in others slowly, after the injection of magnesium sulphate, as is illustrated by the following cases:

In two cases (Cases 7 and 17, Table I) a white opalescent fluid, strongly alkaline and showing no visible trace of bile pigments, was collected five minutes after the injection of magnesium sulphate and was followed by Bile B. In Case 17 the absence of bilirubin was confirmed by chemical examination. In both cases flocculi containing a very large number of cells were present in this white bile-free fluid. In another case (Case 12, Table II) a large number of flocculi containing many cells first appeared in Bile C, which flowed after Bile B. Thus the time of appearance of flocculi and cells in the bile after

the injection of magnesium sulphate would appear to vary, the above cases being the extremes in the present series.

A study of the literature available to us suggests that only two groups of workers have undertaken the necessary control observations—namely, examination of the bile aspirated at operation from the gall-bladder and common duct in patients who had previously been intubated, concentrated magnesium sulphate being the biliary stimulant employed. Knott and Bowell (1924) investigated five cases, and their reports do not show any constant parallelism between the findings in the bile removed at operation and that obtained by medical drainage. In parenthesis it should be noted that Venables and Knott (1924) introduced into the duodenum only 10 c.cm. of a 25% solution of magnesium sulphate instead of 75 c.cm. of a 33% solution as recommended by Lyon. It is not surprising, therefore, that they were unable to confirm Lyon's claim that three distinct types of bile could be recovered (Bile A, B, and C). The small amount of the stimulant used may also explain why the number of cells present in the specimens was often much less than was found by us. Mateer and Henderson (1926) could not find any leucocytes or epithelial cells in the bile aspirated direct from the gall-bladder at operation in 54 cases, though in 51% of the same group they found bile-stained cells in the bile recovered by duodenal drainage after the administration of magnesium sulphate before operation. They regarded these cells as evidence of inflammation of some part of the biliary tract other than the gall-bladder; but this assumption lacks proof, since they did not examine bile obtained from the common or hepatic ducts.

The work of the above authors strongly supports our contention regarding the local irritating effect of magnesium sulphate on the duodenal mucosa and that the cells do not come from the gall-bladder. It should be noted that the necessary comparison of the cytological effects of other biliary stimulants with that of magnesium sulphate in the same patients was not undertaken as an additional control. Our repeated failure to find cells in the bile removed by intubation after the administration of peptone and olive oil, in cases in which many cells were present in the bile obtained after magnesium sulphate, suggested at once a possible fallacy in this diagnostic method.

Summary and Conclusions

A study has been made of the cellular content of: (a) bile removed by duodenal intubation after the administration of magnesium sulphate, peptone, and olive oil in patients with and without disease of the biliary tract; (b) bile aspirated at operation from the gall-bladder and common duct in patients suffering from cholecystitis and cholelithiasis; (c) fluid removed from the mucosa of the human stomach, duodenum, jejunum, and ileum, exposed at operation, which had been submitted to the local effect of saline, peptone, and magnesium sulphate.

From the above experiments it is concluded that the cells present in the bile obtained by duodenal drainage after the administration of magnesium sulphate may be produced by local irritation of the duodenal mucosa, and hence do not necessarily indicate pre-existing inflammatory disease of the biliary tract. Attention is drawn to the fact that the degenerating oval or cuboidal duodenal epithelial cells may closely simulate pus cells.

We wish to express our thanks to our surgical colleagues in the Royal Infirmary for permission to investigate their cases, and in particular to Prof. J. R. Learmonth for his advice and help in the experiments connected with the action of magnesium sulphate on the exposed mucous membrane of the alimentary tract. One of us (J. I.) was in receipt of the McCosh Bursary and Crichton Scholarship in Medicine during the period of this investigation.

[NOTE.—Since the completion of this paper for publication we asked some of our medical colleagues on the staff of the Edinburgh Royal Infirmary to select patients in their own wards who were not suffering from disease of the gastro-duodenal or biliary tracts, in order that we might demonstrate the irritant effects of magnesium sulphate as used in duodenal intubation. Our colleagues watched the technique being carried out and personally made a microscopical examination of the specimens of bile recovered. The results obtained were similar to the findings shown in Table I.]

OBSERVATIONS ON SOME NORMAL AND INJURIOUS EFFECTS OF COLD UPON THE SKIN AND UNDERLYING TISSUES

III. FROST-BITE

BY

SIR THOMAS LEWIS, M.D., F.R.C.P., F.R.S.

Physician to University College Hospital

Frozen Skin

Skin can be frozen in the living subject very readily by bringing it into contact with sufficiently cold metal or by allowing a jet of very cold air to impinge upon it. These methods I used extensively to study the effects of freezing (Lewis and Love, 1926). Freezing of the skin in a current of cold air is recognized by an observer the instant it happens. The patch of skin affected seems at once to become pale, dull, opaque, and of a yellowish colour. The attentive subject recognizes freezing at once when it is due to metallic contact, the formation of ice crystals in the skin being accompanied by a very definite pricking sensation. In a jet of cold air freezing may happen without subjective sensation: or it may be signalled by a little short stinging pain that is felt abruptly in the part. All these observations of the laboratory conform with the experience of sufferers from frost-bite in the open air. Skin that is frozen without involvement of the subcutaneous tissue forms a hard plaque in the skin, with edges which are sharply defined and by which the plaque can be lifted. It feels like a coin embedded in the skin. When the frost extends deeply the frozen tissues are solid and immovable.

Freezing-point of Skin

Although very accurate determinations of the living skin's freezing-point have never been made, this point is known accurately enough for our purposes. It is certain that it lies below the freezing-point of water, and it is equally certain that it is not far from -1°C . The freezing-point of blood serum is -0.53°C ., from which that of skin is unlikely to be far removed. If metal bars at exactly known temperatures are applied to the human skin, freezing can be shown to occur on occasion at a surface temperature as high as -2°C . (Lewis and Love, 1926). Such an observation fixes a temperature between which and 0°C . the actual freezing-point of skin lies.

Supercooling

It is now to be said that skin when cooled very rarely freezes at its true freezing-point. It exhibits in very

remarkable degree the property called supercooling (Lewis and Love, 1926). If the skin is cooled by contact with cold metal it is unusual for it to freeze unless its surface temperature is reduced below -5°C. , and it often happens that this temperature is lowered to as much as -10°C. , and sometimes to -15° or even to -20° , without the occurrence of freezing. It is not merely a matter of surface temperature; the whole thickness of the skin may at times be reduced to -10°C. and remain unfrozen. Freezing will generally occur between -5° and -10°C. if such temperature is maintained; but the actual temperature required and the time for which cold metal must be applied vary greatly, not only from one skin to another, but from point to point of the same skin, and even in successive observations on one and the same small area. Freezing begins with difficulty, but once started it spreads rapidly throughout all the chilled tissue, progressing the more quickly the lower the point to which preliminary cooling has been carried. As in the case of a cooled vessel of water, the formation of the first ice crystals encourages the formation of more, and so water or skin that has already been supercooled quickly becomes solidified once freezing starts.

This power to supercool is normal; it is a very important protection against freezing and the injurious effect that would arise out of this physical change. It has been found that supercooling displays itself in greater degree in skin that remains unwashed. Washing the skin encourages, while rubbing the skin with spirit and anointing it with oil discourages, freezing. The capacity to supercool greatly would seem to be connected with relative dryness of the horny layers of the skin. It is well known that Arctic explorers leave their skins unwashed.

The level of temperature at which skin freezes does not seem to be influenced appreciably by the presence or absence of a blood flow to it; but, naturally, blood flow according to its degree will affect the rate at which the preliminary cooling of the skin occurs.

Natural Frost-bite

The conditions under which natural frost-bite occurs are known to us from the observations of those who have lived in very cold climates. When atmospheric temperature is below 0°C. the air contains no moisture. Frost-bite occurs only when the air is dry and when the ground is snow-clad or frozen. It is frequent in people moving about out of doors when the temperature is as low as -30°C. (-22°F.). The radiant heat of the sun protects against frost-bite. Wind favours its occurrence, for in a still atmosphere the skin tends to become enveloped in a layer of air which the skin itself has warmed; thus Brahdy (1935) speaks of frost-bite as frequent with a temperature of -13°C. (8°F.) if there is wind. Natural frost-bite occurs chiefly in parts of the skin that are exposed and in those parts of such skin that cool most readily. When both are exposed the hands cool more readily than does the face; the fingers, the ears, and the nose cool fastest, and in the order stated. It is customary to give special protection to hands and ears; consequently frost-bite of the nose is relatively more frequent than it otherwise would be. Frost-bite of the feet is relatively unusual, for circulation in the feet is generally maintained active by walking; the feet will suffer if they are kept still in very cold air or in snow for long periods, for when still the feet cool as quickly as the hands. Tight coverings of legs or feet by interfering with circulation encourage cooling and increase the chance of frost-bite. Freezing of feet while immersed in sea-water can hardly occur; for the temperature of the water cannot fall below -1.9°C. , its own freezing-point.

Effects of Freezing

These lesser effects have been described in full detail in my original article with Love (Lewis and Love, 1926). When the skin has been frozen its invariable response when thawed is a state of hyperaemia. The local redness of the skin, due to dilatation of all its small blood vessels, occurs after the lightest freezing. If the skin has been frozen harder—namely, at -10° to -15°C. for about twenty seconds—the local redness is shortly followed by itching and by swelling, and a full wheal develops precisely over the area frozen. This wheal is surrounded on all sides for some centimetres by a bright red flare, the result of reflex vasodilatation. The local reddening, the wheal, and the flare compose what I have called (Lewis, 1927) the "triple response." They are due to the release of a histamine-like substance or substances from the cells of the skin, the release resulting from the injury caused to the skin cells by the ice crystals formed in it; and they together constitute a simple acute inflammation, the typical immediate reaction to physical injury. The wheal gradually subsides within a period of a few hours, leaving behind it an area of local redness. This redness persists, and next day at latest the corresponding skin is a little swollen, is tender to friction, and gives pain when warmed. Sections of the human skin taken twenty-four hours after the injury display a little oedema of both epidermis and dermis, and a perivascular infiltration of the superficial layers of the dermis with lymphocytes, extravasated red blood cells, and some polymorphonuclear cells (personal observations). This infiltration may in some instances be intense enough within a few days to give to the affected skin a yellow colour. Within about a week the tenderness of the skin has subsided and the epidermis has proliferated and presents a crinkled pigmented surface, which soon peels. After peeling, the redness of the skin gradually fades, though pigmentation often persists for many weeks or even months.

Such are the simplest reactions to freezing in the human skin. If freezing has continued at -15°C. for thirty to sixty seconds, or at -20°C. for fifteen or thirty seconds, then the lesion that follows is more severe. Usually the wheal which at first forms gives place within an hour or two to blister, which, curiously, is predicted in the stage of thawing by the occurrence not of itching but of burning pain. Such blisters are associated with a more pronounced exudative inflammation than that described as following the wheal.

Still greater damage occurs when freezing is more severe and more prolonged, for the skin is frozen harder and the frost penetrates more deeply. Corresponding lesions are well illustrated by the effects of freezing the skin with CO_2 snow (the temperature of which is about -57°C.) and by severe frost-bite in man (Hodara, 1896a, 1896b). The results of such freezing have also been extensively investigated in animals, especially in the rabbit's ear, by Cohnheim (1873) and others (Brahdy, 1935; Fuerst, 1893; Hodara, 1896a, 1896b; Kriege, 1889), observations that have enlightened us particularly as to the train of events leading up to loss of tissue. The end-result of severe freezing, where there is deep penetration of the tissues, is necrosis. The blood flow in the milder lesions is not interrupted, but there is general agreement that necrosis is brought about largely through injury to the blood vessels of the skin and subjacent tissues; it is the rule to find thrombi within them* (Kriege, 1889; Hodara, 1896a, 1896b). These are of various kinds—platelet, hyaline, and

* Recklinghausen (1883) is cited to the same effect, but it is not clear that the gangrene in this case followed directly on frost-bite. Rischpler (1900) believes that necrosis can occur without thrombosis.

fibrinous in both the smaller arterioles and the larger arteries and veins—and appear within a few hours of freezing; they have been found in human frost-bite not only in tissue in the process of undergoing necrosis but in tissue on the border of such necrosis, and in tissue where necrosis is threatened.

It is clear from past observation and experiment that freezing at such temperatures as -15° to -20° C. must be continued for a matter of minutes if necrosis of the frozen tissues is to follow. But it is not clear that damage to a given tissue progresses beyond a certain point when freezing in it is prolonged. It would seem probable that freezing brought about at -15° or -20° C. soon enters a stable condition so far as a given small group of cells is concerned, and that damage to the cells concerned is full for that temperature and does not increase steadily with time. It is known in general that lesions become severer with lengthening exposure. But the increased severity of damage to skin as freezing is prolonged is probably due, once a hard frost has been ensured, to extension of freezing to deeper layers of skin and to subjacent tissues, rather than to progressive damage of individual cells. There is, at all events, no evidence to show that a severely frozen limb in which freezing has after a time ceased to extend becomes subsequently damaged in proportion to the time which it remains frozen. Some progress there may be, but almost certainly the chief factors governing the degree of damage are the hardness of the frost and its extent: time, apart from its influence in increasing the freeze, is not known to be a material factor.

Secondary Injury.—There is some evidence that when the skin has been frozen the damage sustained may be added to in the stage of the reaction itself by the rapid outpouring of fluid between the tissue elements (Lewis and Love, 1926). If the venous return from a limb on which a small area of skin has been frozen is obstructed during the stage of thawing and for five minutes afterwards, subsequent whealing is much diminished and seemingly the return of the tissues to a normal state afterwards is expedited (Lewis and Love, 1926).

Treatment of Frost-bite

Our knowledge of frost-bite and the manner in which the skin reacts to it suggests certain measures in its treatment, which will be dealt with briefly.

When the patient is seen at a stage at which the tissues are frozen the first step will be to induce thawing. There are two reasons why this should not be done too rapidly. First, rapid thawing will be followed by intense swelling of the tissue, and this is probably in itself injurious. Secondly, the more rapid the warming the greater will be the pain, and following thawing it may be very severe. The long-established custom of rubbing the frozen part with snow will ensure slow thawing, and its reputed effectiveness probably depends on this fact. But friction is not to be recommended in itself: thawing will not occur unless friction is brisk, and such friction will tend to damage the skin and to increase the reaction. It would seem preferable, when it is practicable, to apply warmth of reasonable amount. It should be no more than suffices to induce thawing under strict control. Thus if the skin is unbroken, cold water, rising to no higher temperature than 10° or 15° C., may be applied safely and will answer the purpose, precaution being taken then and subsequently to prevent the return of a full circulation to the damaged tissues. In the case of a limb, its arteries may be compressed until thawing is complete, and the compression then be relaxed gradually to allow the blood to return to the limb little by little. The temperature of the part that has been frozen can in

this way be raised very slowly, as is desirable, and warmth mainly allowed to come to it through the returning blood. If in the process pain becomes severe it can be moderated by cooling the part once more as the circulation returns to it. The object should be to restore the blood flow and warmth gradually and thus restrain vascular and accompanying reactions.

When this has been effected the limb may be protected by wrapping it lightly with cotton-wool or lint, covering it with a cradle, and maintaining around it a reasonably cool temperature. Further treatment will be demanded by blisters and by necrosis with ulceration. From this standpoint it should be recognized that between the lesions following freezing and those following heat there is no fundamental distinction. All such lesions are the result of greater or lesser injury of cells of the skin and of deeper integuments, injury which brings partial or complete disintegration of the cells. The reactions that follow are not properly regarded as reactions to frost or to heat, but to tissue injury. The heating and the freezing are transient, and the reactions we see are the reactions to what heat and frost leave behind them. In both instances the reaction is a response to substances released largely from living cells and in part from killed cells. It is true that heat differs from frost in that it has the power to coagulate the tissues and in the end to consume them; but the important fact remains that the reactions, as we trace them through different grades of severity and compare equal grades, are fundamentally alike: local redness, wheal, flare, blister, cellular exudate, vascular thrombi, and necrosis appear in each, as do the appropriate processes which isolate and separate off dead tissue and lead to repair.* The presence of incinerated tissue in the case of injury by fire is the only notable difference and one that has no high importance; this difference does not exist in a comparison of freeze and scald.

It follows from what has been said that the rational treatment of the lesions of frost-bite and scald have much in common. The appropriate routine treatment of one or other state must of course be governed ultimately by one consideration only—namely, by its proved effectiveness. But in considering new means of treating, theoretical considerations can guide. A guide to the treatment of lesions following frost-bite which I would strongly recommend is that they should be dealt with in the same way as are similar lesions resulting from heat, in respect of the treatment of which we possess much recent experience.

S. B. Lovelady, J. R. McDonald, and J. M. Waugh (*Amer. J. Obstet. Gynec.*, 1941, 42, 309) made a study of thirty-four benign growths of the vulva which had been removed at the Mayo Clinic from 1906 to 1939 inclusive. The commonest types were fibromas, lipomas, and haemangiomas. Two neurofibromas, two leiomyomas, a ganglioneuroma, and a lymphangioma were also encountered. A striking feature was the lack of symptoms produced by the tumour in the majority of cases.

AN EXPERIMENTAL STUDY OF THE WOUNDING MECHANISM OF HIGH-VELOCITY MISSILES

BY

A. N. BLACK

B. DELISLE BURNS, M.R.C.S.

AND

S. ZUCKERMAN, D.Sc., M.R.C.S.

(For the Research and Experiments Department, Ministry of Home Security)

The fact that the amount of tissue destruction caused by small high-velocity bomb splinters may be out of all proportion to their size has been recognized for some time, and was the subject of correspondence in this *Journal* (1940, July 13 and 27). More obvious explanations of the disproportion between size of wound and size of missile—for example, that it is due to the irregular shape of the splinters and to their rotary movement (Wilson, 1940)—appear inadequate to explain the phenomenon, and it was therefore suggested (Zuckerman, 1940) that a more reasonable interpretation lies along the lines suggested by Cranz and Becker (1921) in their analysis of the effects of high-velocity missiles in soft media. If the physical explanations of Cranz and Becker are applicable to splinter wounds in flesh it would appear that the destructive effect of a small splinter is due to the motion imparted to the soft medium through which it passes, as a result of which the tissue is moved away violently from the track of the missile, an effect being produced similar to that of an internal explosion.

Observation also shows that splinters have little rotary effect in those media in which their effect has been studied. It has been found, too, that non-spinning projectiles fired from a smooth bore have an explosive effect in media such as mud (Cranz and Becker). It is thus improbable that the damage which occurs in the neighbourhood of the actual track of a splinter would be seriously altered by any peculiarities of shape or by any rotation. On the other hand, shape and rotation could undoubtedly have an effect on the track itself.

The experiments described in this paper have been designed to test this interpretation.

Method

The investigation was carried out on rabbits and on blocks of 20% and 5% gelatin. The former dilution was chosen as it corresponds to the dilution of protein in the body.

With the facilities available to us it proved impracticable to devise a splinter gun capable of firing irregular-shaped fragments of metal at high velocities in such a way that they could be accurately aimed. It was also impracticable to perform the experiments with model bombs. Accordingly a gun was devised (by Colonel P. Libessart of the Free French Forces) capable of firing, with a cordite charge, a 3/32-inch steel ball weighing 53 mg. at velocities varying between 500 and 5,000 f/s. The choice of this standard missile was to some extent arbitrary. In weight it corresponds to a very large proportion of the splinters which are shot off from any bomb or shell. It is possible, by means of relationships that have been worked out in other fields of ballistic study, to equate approximately some effects of the ball with those which would result from the penetration of any irregular-shaped splinter.

The velocity of each shot was measured by means of the Boys spark-photography method. The essential feature of this method is that the missile cuts a wire forming part of an electrical circuit, and thereby, through a relay, discharges a condenser across a spark gap. By using 10,000 volts enough light is obtained from an exposure of less than 1 microsecond to throw a shadow of the missile and target upon photographic paper. The impact and residual velocities of the missile are measured from the sound waves which are thrown off and which are photographed on the paper. By varying the interval between the impact of the missile on the target and the cutting of the wire, shadowgraphs of the target can be obtained at varying times after it is hit. Using identical targets for successive shots, it is thus possible to photograph the successive changes which take place in a target during the fraction of the second after it is struck. The present paper deals with such records.

Results

Blocks of gelatin 4 cm. by 4 cm. by 5 cm. were made by pouring a warm 20% solution of gelatin in water into moulds. Figs. 1 to 6 show silhouettes of the gelatin at varying times after the ball hit the front face of the block. Before each shot was fired control shadowgraphs were made, and these are outlined in each figure to give a measure of the distortion undergone by the gelatin block after its penetration by the ball. The magnification of the stages in each series of photographs varies; the dotted outline in each case, however, represents the same size of target. Unfortunately it was impossible to follow the cycle of changes through to the end because the blast of the gun, which follows behind the missile, forms a shadow that obliterates the gelatin block in the photograph. The blast actually helps to blow the gelatin block away. Each target was, however, recovered immediately after the shot was fired.

It will be seen that as soon as the ball enters the target a tail splash develops. This increases in size in the interval taken by the ball to traverse the block. As the ball emerges it pushes before it a head-cone which it ultimately leaves. This is the only distortion which occurs during the few microseconds taken by the ball to pass through the target. Immediately after complete perforation has been achieved, however, the block of gelatin undergoes considerable expansion, until it becomes some three to four times its original volume. In spite of this distortion the blocks return to their original size and shape. The only permanent visible effect of the shot is the small thread-like track made by the passage of the ball. This track is the same in appearance as that caused by pushing a needle through the block. Occasionally a few small bubbles of air and small radial fractures may be seen in the track. Experiments with similar blocks of 5% gelatin gave the same result.

A corresponding series of photographs were made of cylindrical 20% gelatin blocks shot diametrically. The changes demonstrated were the same as those shown by the rectangular blocks. In this series of observations shadowgraphs of the same target were made simultaneously in a plane at right angles to the usual plane of photography. This was done by reflecting, by means of a mirror, the light from the spark on to recording paper placed beneath the target. These additional shadowgraphs showed that the size of the target increases in all directions.

A third series of observations on identical cylindrical blocks of gelatin enclosed in a skin made of the inner tube of a bicycle tyre showed that the distortion for similar time-intervals after the first impact of the shot was considerably reduced, the reduction presumably being due to the resistance of the "skin" to the expansion of the gelatin.

Figs. 1 to 6 show shadowgraphs of rectangular gelatin blocks 4 cm. by 4 cm. by 5 cm. during and immediately after penetration by a 3/32-inch steel ball travelling at velocities between 700 and 1,000 m/s (2,296 and 3,280 f/s). In all the figures the dotted line shows the outline of a shadowgraph of the target immediately before shooting.

Fig. 7 shows the outline of the hind limb of an anaesthetized rabbit immediately before and a shadowgraph of

whole process occurring with explosive violence. In this way a central cavity, the pressure of which is presumably sub-atmospheric, is formed within the target. The peak of the change occurs after the missile has completely penetrated the target. It can be estimated from the series of tests on the 4 cm. by 4 cm. by 5 cm. gelatin blocks that 800 microseconds after impact the gelatin is distributed in a peripheral layer averaging about 0.5 cm. thick and surrounding

the limb 550 microseconds after the impact of the steel ball. The limb shows the same type of distortion as the gelatin blocks. At the time of the shadowgraph the ball had completely traversed the limb.

Discussion

The changes which occur in the gelatin blocks can only be explained as being due to the formation of a cavity within the blocks with explosive violence. As the missile passes through the block it imparts motion to the particles in its track, and these fly off radially, imparting their momentum in turn to further particles (and so on), the

a central cavity approximately 5 cm. in diameter. The stresses imposed on the gelatin when struck must be great compared with those that it would be able to resist for a period longer than that in which the cycle of changes occurs. Nevertheless, it is surprising that there is so little evidence of damage in the gelatin blocks when the cycle of distortion is complete.

It has been shown experimentally that the cavitation caused in soft clay by high-velocity missiles is not due to the pressure of air drawn in behind the bullet (see Cranz and Becker). Thus there is no cavitation when a bullet is fired into a clay target down a prepared tubular track

with a diameter slightly greater than the calibre of the bullet. Furthermore, the explosive effect is also observed when a bullet is fired through a soft medium kept in a vacuum. But, on the other hand, the cavitation which occurs in a soft medium is almost certainly responsible for the drawing in of air, some of which may be pushed out again when the target returns to its previous shape. Air may be left in the track, as is shown by the subsequent presence of a few minute bubbles in the gelatin blocks. Small bubbles are also sometimes observed in splinter wounds in flesh.

The fact that the shadowgraphs of animal limbs are essentially similar to those of the gelatin blocks suggests that precisely the same changes occur in human or animal tissues that are traversed by high-velocity missiles. The distortion to which they are subjected can only be likened to that of an internal explosion, and at the height of the deformation, which occurs after the missile has left the part, the tissues must be stretched around a central cavity of relatively large dimensions. Under such conditions it is obvious that structures at great distances from the track of the projectile can suffer damage.

It is a common clinical observation, and one which we have confirmed experimentally, that minute puncture wounds, caused by small bomb splinters, in the skin on the entry and exit surfaces of a limb or other part of the body are often the only external signs of relatively serious internal injury. Our experiments with rubber-coated cylindrical blocks of gelatin provide a parallel to this observation in so far as only minute punctures are made in the rubber covering, in spite of the considerable immediate distortion of its contents. On the other hand, when the steel ball is fired at high velocity at the skinned limb of a dead rabbit or at a slab of meat a large crater is formed in the flesh on the entry side, and the destruction is much greater than in a corresponding part covered by skin.

The explosive character of the forces set up by the high-velocity ball in its passage is manifested not only by the amount of tissue destruction caused but also by the fact that we have often observed comminuted fractures of the femur of a rabbit even when the path of the projectile lay more than 1 cm. from the bone. These fractures can be explained by the fact that bone is relatively non-elastic, and that it fractures as a result of the stresses to which it is subjected by the explosive formation of the cavity along the path of the missile. In the same way we have found that heavy glass plates placed in contact with the gelatin targets, and at a distance of 2 cm. from the track of the ball, are shattered. It would be of interest to discover whether similar indirect fracturing of bone occurs in war casualties.

In contrast with bone, highly elastic structures such as arteries, veins, and nerves are apt to escape injury in wounds caused by high-velocity missiles. Thus post-mortem examination of exposed animals shows that larger vessels and nerves may run intact through regions in which muscle and smaller vessels are often much damaged. It is only rarely that we have observed relatively severe haemorrhage from larger arteries in wounds caused by the ball travelling at 2,500 f/s and upwards, whereas the impression so far gained in our work is that such haemorrhage is not uncommon in wounds caused by the ball when travelling at, for example, 1,500 f/s.

In further experiments we have found that a steel ball, travelling at a velocity of 2,400 f/s through a gelatin block in which is embedded an excised strip of artery containing fluid maintained at a pressure of 100 mm. Hg, will not rupture the vessel, in spite of the distortion of the block, except when the ball actually hits it.

Although larger nerve trunks appear to remain anatomically intact in high-velocity wounds, it should be remembered that they have momentarily undergone considerable stretching around the cavity caused by the missiles. This stretching may be a cause of the transient paralysis and analgesia which is sometimes said to occur as a result of bomb-splinter wounds, for it is known that a nerve can lose its conducting properties for some time after such distortion.

Summary

Experiments suggest that the disproportionate degree of tissue destruction caused by small high-velocity bomb splinters is due to the fact that particles lying in their path are thrown radially with sufficient violence to leave a central cavity around which tissues at some distance from the track are momentarily stretched. While blood vessels are usually elastic enough to experience this strain without anatomical and apparent functional injury, and nerves without obvious anatomical injury, bones are often broken at some distance from the track.

Our warmest thanks are due to Colonel P. Libessart, Free French Forces, whose design of the gun and assistance with the photographic technique made this work possible. We also wish to express our gratitude to Miss B. Hunt for her technical assistance.

BLOOD-PRESSURE-RAISING REFLEXES IN HYSTERICAL ANAESTHESIA

BY

J. VERNEY CABLE, M.D., M.R.C.P.

AND

F. H. SMIRK, M.D., F.R.C.P.

(From the Department of Medicine, University of New Zealand, Dunedin)

This paper is concerned with a study of two blood-pressure-raising reflexes in a case of hysterical anaesthesia. These are: (1) a reflex from skin described by Hines and Brown (1932), who showed that when the hand and forearm are plunged into water at 4° C. the blood pressure is raised reflexly as a result of the stimulus; (2) a reflex from muscle described by Alam and Smirk (1937), which depends on the fact that if ischaemic muscles are exercised the accumulation in them of metabolites leads reflexly to an increase of the blood pressure.

It was thought that it would be of interest to investigate a patient with hysterical anaesthesia by observing whether stimuli applied to an anaesthetic area gave rise to objective manifestations such as increase of the blood pressure. In the case described the skin was at first anaesthetic, later analgesic but not anaesthetic, and the muscle was hyperaesthetic.

The subject of our investigation was a married woman aged 35, with one child. There was a long history of various ill-defined abdominal complaints, which had been treated with little improvement by a number of gynaecological operations. The personal history revealed a background of much domestic friction, the patient having been twice married, and seemingly being little happier with the second husband than with the first. Following a domestic crisis she again became ill, and was admitted for investigation, when it was found that there was a complete cutaneous anaesthesia to pain, heat, and cold over the whole body surface supplied by spinal segments. The patient stated that she had been unaware of this condition until her attention was drawn to it during examination in hospital. There were no other signs to suggest any organic lesion of the nervous system. The Wassermann reaction was negative. Explanation to the patient

that the disorder was functional and suggestion that skin sensation would return be succeeded by a prompt renewal of the capacity to detect pin-pricks and some slight return of the capacity to distinguish differences of temperature; but the complete cutaneous analgesia remained undiminished, and neither deep pin-pricks nor prolonged contact with ice led to pain, discomfort, or change in facial expression.

Method of Investigation

With the patient lying in bed a series of measurements of the blood pressure were made on the right arm; the left arm (which in common with other parts was devoid of superficial sensation) was placed out of view of the patient. When the blood pressure had reached a steady level a sphygmomanometer cuff placed previously around the upper arm on the left side was inflated to 170 mm. Hg—a pressure well above the patient's systolic pressure—thus completely arresting the circulation through the left arm. For the elicitation of the Hines and Brown blood-pressure-raising reflex small blocks of ice were packed around the patient's left arm, taking care that the operation was inaudible as well as invisible. The general blood pressure was measured again in the right arm while the left arm was being stimulated by the application of ice. To investigate the effect of the blood-pressure-raising reflex from muscle the patient opened and closed the left hand with the circulation through the left arm completely arrested until pain of the intermittent claudication type prevented further movement. During the exercise and for some time afterwards measurements of the general blood pressure were made on the right arm.

Results and Discussion

It was found that after the application of ice to the left arm the blood pressure in the right arm began to rise, although the patient felt no discomfort whatsoever from the ice. The increases in blood pressure averaged 17 mm. Hg systolic and 11 mm. diastolic. The protocol of one of these investigations is here set out; three such investigations were made on different days, always with a rise of blood pressure. In order to ensure that the rises of blood pressure were not of psychological origin care was taken to prevent the patient seeing or hearing that anything was being done to the limb. During the investigation the patient's reports of her sensations were either that she felt nothing whatsoever or that something was felt, though not of a painful nature. In the normal person the pain arising from the application of several blocks of ice to the hand and forearm usually becomes almost intolerable

Protocol showing the Effect upon the Blood Pressure of the Application of Ice to a Limb with Skin Anaesthesia of Hysterical Origin

Time	B.P. Readings in Right Arm	Time	B.P. Reading in Right Arm
4.12 p.m.	138/105	4.17 p.m.	150/118
	142/104	4.18 p.m.	156/120
Sphygmomanometer cuff round left arm inflated to 170 mm. Hg			
4.13 p.m.	144/104	Ice removed and cuff round left arm deflated	
4.14 p.m.	144/105	4.19 p.m.	138/106
Ice applied to left forearm and hand			
4.15 p.m.	148/98	4.20 p.m.	144/110
4.16 p.m.	147/110	4.21 p.m.	146/110
		4.22 p.m.	141/107
		4.23 p.m.	140/104

within less than one minute. In this hysterical patient no pain or discomfort whatsoever followed the application of ice to the hand and forearm, yet the normal reflex increase of blood pressure was not abolished by hysterical loss of the patient's capacity to feel this painful stimulus. It was concluded that the rises in blood pressure were of a reflex nature, since, with the circulation of the limb arrested, nerves form the sole channel of communication between the limb and the rest of the body. While eliciting the reflex from muscle it was observed that muscle pain was induced with unusual ease, since twenty-five contractions of the left forearm muscles, effected by opening and closing the left hand during arrest of the circulation in the left arm, gave rise to strong pain of the intermittent claudication type, which was associated, as is usual, with a reflex rise in blood pressure. In a normal person twenty-five

strong clenchings of the hand with the forearm ischaemic will not elicit appreciable claudication pain.

Investigations have shown (Alam and Smirk, 1938) that the blood-pressure-raising reflex of Hines and Brown (in which cold is applied to an arm) cannot be elicited from an area in which there is local loss of sensation of organic origin, and it would appear, therefore, that if the observation we have made is of general application the presence or absence of this blood-pressure-raising reflex from skin might provide evidence in doubtful cases as to whether an area of skin anaesthesia was the result of an organic lesion below medullary level or was hysterical in nature. The observation is of further interest in that it demonstrates the integrity of certain nervous pathways in a patient with hysterical skin anaesthesia, and indicates that a similar method of study is applicable to cases in which there is loss of muscle pain.

Should observations such as these be employed in the differential diagnosis of nerve lesions it is of importance to recognize that emotional stimuli also produce striking changes in blood pressure and that the degrees of reflex increase in blood pressure vary considerably, but are seldom less than 10 or more than 50 mm. Hg.

Summary

Observations have been made on a patient with superficial anaesthesia of a hysterical nature, including the skin of the left arm. It was observed that the application of ice to the left arm caused a rise of blood pressure which was shown to be of reflex origin.

If the patient is unaware of the application of the stimulus a rise of blood pressure on applying cold to an anaesthetic area may be taken to demonstrate the presence of a nervous connexion between the anaesthetic area and the central nervous system, and in some cases would suggest that the anaesthesia is of a hysterical nature.

TEMPORARY VASCULAR OCCLUSION ENDING FATALLY IN URAEMIA

BY

ALAN M. GLEN, M.B., Ch.B.

Senior House-surgeon, County Hospital, Lincoln

In view of the recent work on renal failure after compression injuries a case in which temporary occlusion of the vessels to the right leg was followed by uraemia and death seems worth recording.

Case Report

A workman aged 39 was admitted to hospital shortly after falling some twenty feet through a factory roof on to a concrete floor. He had not been unconscious, was only mildly shocked, and complained of pain chiefly in the right thigh. On examination little was found apart from a contusion over the right greater trochanter and marked limitation of movement of the right hip-joint. He was removed to the ward, and while waiting to be radiographed his condition began to deteriorate rapidly. The routine shock treatment was therefore supplemented by the rapid intravenous administration of two pints of blood plasma, with much benefit—the pulse rate dropping to below 100 a minute and the systolic blood pressure rising to 95 mm. Hg. A third pint was then given by slow drip.

At this time the right lower limb was noticed to be slightly blue and swollen and somewhat colder than its fellow. The inguinal ligament of that side felt tense and appeared to be pushed up from below. Above it the external iliac vessels

were pulsating strongly, but below it no impulse could be elicited in the femoral, popliteal, or post-tibial regions. The limb was flexed slightly at the hip-joint, and the foot was raised in the hope that this might relieve the obstruction; but the bluish tinge persisted, the leg grew colder, and cutaneous sensation was gradually lost. The patient complained of desire to pass water and of inability to do so, but was discouraged from making any attempt until damage to the bladder and urethra could be ruled out. A soft rubber catheter was passed into the bladder easily and 5 oz. of clear urine withdrawn.

X-ray examination revealed a central dislocation of the right hip-joint, with comminution of the floor of the acetabulum, and fractures of both pubic rami of the same side. The head of the femur appeared to be entirely within the cavity of the pelvis. It seemed reasonable, therefore, to assume that the external iliac vessels had either been torn across or been compressed between the fractured superior pubic ramus and the inguinal ligament.

Four hours after admission the external iliac vessels were exposed by extraperitoneal approach under local anaesthesia and found to be undamaged and pulsating strongly. Just below this level they were completely obstructed by being forced upwards against the inguinal ligament by the fractured superior pubic ramus. The inguinal ligament was therefore divided at its midpoint and the circulation in the femoral vessels re-established, but almost immediately the patient collapsed. The pulse disappeared at the wrist, his colour became ashen, and his breathing was gasping in character. Pressure was at once reapplied to the released vessels, the head of the table lowered, and 1/2 grain of ephedrine given intramuscularly. In a few minutes the pulse returned at the wrist, his colour improved, and the breathing became quieter. The vessels were therefore intermittently released for a few seconds at a time and the horizontal position gradually reassumed. A further pint of serum was given, making a total of four pints, and the wound closed. The patient returned to bed in good condition, and overnight received a litre of 5% glucose saline intravenously.

The following day he appeared well, complaining only of the tingling in his leg, which was a good colour and about the same temperature as its fellow. It had, however, a peculiar feeling of hardness, almost as if the underlying muscles were being held in contraction. The femoral pulse was satisfactory, but no pulse could yet be elicited in the popliteal or ankle regions. Under local anaesthesia a Steinmann pin was passed through the tibial tubercle and an initial traction of 10 lb. applied with the hip abducted and slightly flexed. By evening the colour had returned to normal, the posterior tibial artery was pulsating, and cutaneous sensation was beginning to return.

In spite of a fluid intake of over two pints a day by mouth, the amount of urine secreted on the three days following operation was 6 oz., nil, and 2 oz. respectively. Both samples were acid in reaction and heavily blood-stained. The bowels were somewhat loose, and moved twice daily. There was no evidence of oedema. On the evening of the third day his condition began to deteriorate. He became drowsy, with intervals of acute and increasing anxiety and short attacks of dyspnoea. The following morning there was occasional retching but no actual vomiting. He was more drowsy, but still had intervals of acute anxiety, and frequently expressed fear of impending death. Examination revealed no evidence of oedema or of pulmonary complications, but a blood-urea test made at 10 a.m. gave a reading of over 200 mg. per 100 c.cm., and at midday the patient died, just under four days after the accident.

Post-mortem Examination

A necropsy was performed two hours after death and the findings are briefly as follows:

The peritoneal cavity contained a small amount of free blood, probably due to two small superficial lacerations of the spleen. The comminuted fracture of the pelvis was confirmed, and the upper pubic ramus was found thrust against the inguinal ligament with the external iliac vessels arching over it. These vessels were undamaged. The head of the femur was entirely within the pelvic cavity, and there was a fairly extensive retroperitoneal haematoma in the pelvis and extending up the posterior abdominal wall. The muscles of the affected leg appeared normal. The bladder, ureters, and kidneys were un-

damaged, though the last-named appeared extremely congested. All other viscera were healthy. Microscopical examination of sections taken from both kidneys revealed gross pathological changes. The glomeruli for the most part seemed normal, though in a few the capsular space contained clear structureless material staining pink with eosin. The tubules, however, showed profound degenerative changes of the lining cells, with pyknotic nuclei and granular degeneration of the cell contents, most pronounced in the proximal tubules. More distally the tubules contained darker-staining reddish-brown material, for the most part coarsely granular but some of it homogeneous, and in a few suggestive of clumped degenerating erythrocytes. The proportion of tubules so affected increased as the pelvis was approached, and in many fields towards the apex of a pyramid over 80% of the tubules seen appeared to be choked with this granular material.

Summary and Comment

This is a case of central dislocation of the hip with fracture of the pubic rami of the same side causing obstruction of the external iliac vessels. Relief of the obstruction by dividing the inguinal ligament was followed by sudden and profound collapse comparable to that resulting from the sudden release of a tourniquet left over-long in position.

Death resulted from uraemia within four days of the accident, and the microscopical appearances of the kidneys corresponded closely with those recently described in cases of crush injury (Bywaters and Beall, 1941; Beall, Bywaters, Belsey, and Miles, 1941; Mayon-White and Solandt, 1941).

The hardness of the limb noticed after operation is interesting in view of the theory recently put forward by Patey and Robertson (1941) that the syndrome may be due to loss of substances from the circulation into the injured limb. Unfortunately no particular attention was paid to this aspect at the time.

It is hoped that the findings described may prove of interest to those investigating such cases and to others who may have to deal with similar injuries.

I wish to thank Mr. G. A. Bagot Walters for his advice and for permission to publish this case; also Mr. Chandler for the blood chemistry and the preparation of sections.

The province of Sind in North-West India, the population of which is just over four million, has a lower birth rate, death rate, and infant mortality rate than any other Indian province. The latest annual report on public health in Sind gives the birth rate as 20.88, the next lowest being Assam with 29.92; the death rate is 11.55, the next lowest being the North-West Frontier with 18.74; and the infant mortality rate 105 per 1,000 births, as against 130 in the North-West Frontier. For the second year in succession the chief city, Karachi, enjoyed immunity from plague in 1939. What are described as "fevers" accounted for the greatest number of deaths; this category includes many of the deaths due to malaria. Malaria is the disease most prevalent in the rural areas, and is one of the major problems of the province. Its prevalence has been accentuated by the enormous increase in the area brought under cultivation since the opening of the Lloyd barrage. Vigorous anti-malaria measures are being taken, and during the year under review nearly two million 5-grain tablets of quinine sulphate and four and a half million 2-grain tablets, manufactured at Hyderabad central prison, were supplied for distribution. Next to "fevers," respiratory diseases account for the largest number of deaths. An active anti-tuberculosis campaign is in progress, and clinics in charge of fully trained tuberculosis medical officers are being established in each of the district towns. Cholera was restricted to one village in the Hyderabad district, and only six cases and three deaths were reported. Small-pox is prevalent and accounted for 565 deaths. Trouble is encountered in administering the vaccination laws.

Medical Memoranda

Iodine Ointment for Epidermophytosis Interdigitale

Epidermophytosis interdigitale, or "athlete's foot," is one of the commonest minor ailments encountered in the Army, and the more severe cases occupy a large number of beds in the skin wards of military hospitals—at least in the Transvaal. I have not had experience of the incidence among soldiers in temperate climates, but one would be safe in assuming that it is much more common under the tropical and subtropical conditions of the African continent. In temperate zones its occurrence is almost confined to the summer months, whereas in warmer climates it occurs in winter as well as in summer. Sweating of the feet, unavoidable when long route marches are undertaken in hot weather, predisposes to epidermophytosis interdigitale, and a considerable incidence of the condition is inevitable in any tropical campaign.

A period as a regimental medical officer, followed by a period in charge of the skin beds at a large military hospital serving a South African military camp, has provided me with the opportunity of seeing large numbers of cases of both the earlier and the more severe stages. It was my impression that the incidence was at least 30% in the regiment to which I was attached. The regiment had been called up six weeks previously. The institution of simple precautionary measures, such as scrubbing the floors of the showering cubicles with disinfectant, the issuing of boric powder, with instructions to powder the feet in the morning before donning the socks, the washing of feet after excessive sweating, and thorough drying between the toes after washing, served to reduce the incidence considerably. Despite all these precautions a large number of men still developed the condition.

At first Whitfield's ointment was the routine treatment used, but cases arose which failed to respond to it. Castellani's paint was not obtainable, and in view of the fact that iodine is a good fungicide I decided to try ung. iodi denigrescens (iodine 87½ grains, arachis oil 288 minims, yellow soft paraffin ad 4 oz.). The edges of the opaque white sodden skin were cut away and the ointment was rubbed in well but gently; the affected area was then dusted with boric acid powder. Many of the cases which had failed to respond or were responding tardily to Whitfield's ointment cleared up rapidly with the iodine ointment. It was then decided to try the effect of this ointment in the early stages, and it was found that often in early cases with commencing fissures two and sometimes one application resulted in the complete disappearance of the condition.

Subsequently, in the more severe cases admitted to hospital it was possible to institute a more controlled investigation. In bilateral cases Whitfield's ointment was used on one foot and iodine ointment on the other. Almost without exception the iodine ointment was more effective than, or at least as effective as, Whitfield's ointment. A similar experiment was then conducted using iodine ointment on one foot and Castellani's fuchsin paint on the other. Here the results were not so unequivocal. Most of the cases responded more rapidly to the iodine ointment, but there were some severe cases which responded sooner to Castellani's paint. The ointment has the advantage of being cheaper, more easily obtainable, and not so readily spilled. At the very least it provides a useful alternative treatment for a condition that can be a source of great trouble under Army conditions.

Ung. iodi denigrescens was also tried in the treatment of cheilompholyx of fungous origin, with very satisfactory results.

M. M. Baumgartner and T. O. Nuzum (*Wisconsin med. J.*, 1941, 40, 579) review the literature and record a case of infectious meningitis in a woman aged 39 who had a good recovery after spinal drainage and oral administration of sulphamylamide.

Reviews

A TEXTBOOK OF ENDOCRINOLOGY

Essentials of Endocrinology. By Arthur Grollman, Ph.D., M.D. (Pp. 480; illustrated. 36s. net.) Philadelphia, London, Montreal: J. B. Lippincott Company. 1941.

Textbooks of endocrinology appear so frequently that it is legitimate to inquire the reasons for yet another one. We can supply Prof. Grollman with better reasons than those he gives in his own preface. In the first place we approve of his biological approach, which is not sufficiently stressed as a rule. As an example he groups the thyroid, parathyroids, and thymus together as the branchiogenic organs in a way which will appeal to those who feel that the comparative anatomist can throw much light on the evolution of the endocrine system. Then he is not afraid to be both dogmatic and sceptical; the former quality is necessary for the student, the latter for the practitioner. Also he devotes more than a third of the book to the gonadal hormones, which is appropriate, for this is the most actively advancing branch of the subject, and one which it is difficult to find related so coherently. This is the best section of the book. In some respects Prof. Grollman has not allotted the rest of his space so successfully: thus only a single page is devoted to the history of endocrinology in general; only half a page is given to the therapeutic uses of adrenaline, and nearly three pages to the rare tumours of the adrenal medulla. Diabetes is included, as is logical, and it enables him to contrast it with hyperinsulinism and von Gierke's disease. The whole work is more readable than some textbooks on the subject, and it can be recommended to students and practitioners alike.

OTO-RHINO-LARYNGOLOGY

Diseases of the Nose, Throat and Ear. A Handbook for Students and Practitioners. By I. Simson Hall, M.B., Ch.B., F.R.C.P.Ed., F.R.C.S.Ed. Second edition. (Pp. 446; illustrated. 15s. net, postage 7d.) Edinburgh: E. and S. Livingstone. 1941.

There has been a call for a second edition of this book within the space of four years. The author has made no important change and the increase in size is very slight, due to some fresh illustrations. The excellent coloured plate showing diseases of the tympanic membrane—the frontispiece of the first edition—has been eliminated, but some less instructive photographs have been retained, such as Fig. 25, which shows puncture of the antrum with trocar and cannula but without the aid of a nasal speculum. In spite of this we are not persuaded that the author really practises this blind procedure. Tracheotomy is now illustrated. A very long incision is shown extending over the larynx. Certainly the incision should be long enough, but not longer than is necessary. The tube recommended, and now shown in a figure, is Jackson's. This model does not conform to the configuration of the neck and is a constant source of trouble. Durham's tube has long been recognized in Great Britain as possessing the proper shape and should almost always be used, though it is more expensive to manufacture.

For laryngotomy the author advises a tracheotomy tube. It may be necessary to resort to this makeshift in an emergency, but for laryngotomy a laryngotomy tube should be used. In the section on the ear a generous amount of space is devoted to the intracranial complications of otitis media, but otitic encephalitis still receives no mention. Failure to recognize it leads to unnecessary and often harmful explorations of the brain for abscess, and the omission indicates that aural surgeons in general remain

unaware not only of its importance but even of its occurrence. The catch-phrase "oedema of the glottis" should be as obsolete as "perityphlitis" or "bronchocele." Was it not in Edinburgh that the swelling of the lax tissues in the aryepiglottic folds, which causes acute laryngeal obstruction, was first precisely and accurately described?

Notwithstanding these criticisms, the book presents a fairly reliable outline of the subject, and no doubt will continue to meet the needs of students for some years.

ALCOHOLISM

What Price Alcohol? A Practical Discussion of the Causes and Treatment of Alcoholism. By Robert S. Carroll, M.D. With preface by Adolf Meyer, M.D., LL.D., Sc.D. (Pp. 362. 12s. 6d.) New York and London: The Macmillan Company. 1941.

However excellent in intention, this book is marred in the performance. No one would question Dr. Carroll's intense sincerity and his deep conviction of the evils of alcoholism. He realizes how frequently this addiction is based on a psychoneurotic temperament which, finding the stresses of life too hard, takes the easiest way to ignore those stresses. He is aware of some of the disasters that Prohibition brought on the United States, but he might have laid more emphasis on the way young people especially took to drink during Prohibition as a declaration of liberty, and on the power which fell into the hands of the bootlegger, who was the parent of the gangster. The bitter lesson had to be learned that it is impossible for the law to go too far ahead of popular approval. We are also heartily with him in his demand for "freedom not to drink," and his claim that it should be no more regarded as an unsocial act to decline alcohol than it is to refuse sugar in one's tea. That "rounds" of drink mean that many take more than they wish and that the weaklings are caught in the toils before they are aware is only too true. But all this is set out with an intolerable degree of repetition and illustrated by cases described in the language of melodrama. Some of his stories are almost incredibly naïve—such as that of the good little boy who signed the pledge at the age of 6 and made such a success of his life. Surely Dr. Carroll must see that this boy was the type who would never have taken to alcohol, and that if he were not of that type a pledge signed before he understood what it meant would not have restrained him. For the drink crave the author recommends half to one ounce of castor oil, repeated if necessary in six hours. Castor oil as a political argument we are familiar with, but we doubt its power to make life easier for a psychoneurotic failure.

Notes on Books

The eighth edition of Prof. R. A. FISHER's textbook of *Statistical Methods for Research Workers* continues the process of revision without alteration of numbering of sections, tables, or examples which is so convenient. Between the fourth and the present edition about forty pages have been added, introducing new methods or extensions of older methods. It is superfluous to say that this manual is a standard work. The publishers are Oliver and Boyd of Edinburgh and London, and the price is 16s.

Chapters 4 and 5 in Dame MARY SCHARLIEB's once popular little book on *Change of Life* still echo the practical wisdom of that great lady. Chapter 6 deals with treatment, but no mention of radium has been inserted even in the 1941 edition (Faber and Faber, 3s.). The foreword written for it states that the book is still perfect, the only fresh knowledge being that "science has lately put on the market an artificial chemical substance to take the place of the normal hormone (i.e., the internal secretion) of the dwindling sex glands. . . . If the symptoms are too unbearable consult your doctor and he can order you the new chemical substitute—stilboestrol."

Preparations and Appliances

A NEW TYPE OF CANNULA

Dr. ARTHUR GUEST, M.R.C.P., sends the following illustrated description of a cannula for blood transfusion and blood withdrawal which he has designed.

For the Intravenous Administration of Blood or Other Fluids without Vein Exposure

The following features are incorporated: The cannula (gauge 17 S.W.G.) is fitted with a hollow needle instead of a solid stylet. This inner needle is of standard pattern, the length being such that, when fully inserted into the cannula, the bevel point just protrudes beyond the blunt end of the cannula. To this needle a small (2 c.cm.) Record syringe is attached during introduction (see Fig. 1). The length of the combination gives very

good control while seeking the vein, and confirmation of venepuncture can be obtained by sucking back a little blood into the syringe.

I have adopted the following procedure: (1) A small intracutaneous bleb of 2% procaine solution is introduced through a fine hydropenic needle at the chosen site. (Not essential.) (2) After a light tourniquet has been applied, the cannula, with the syringe attached, is introduced through the bleb of procaine and the vein is sought and just entered. (3) After confirming entry by sucking back a little blood into the syringe, the inner needle is withdrawn about an eighth of an inch, while the cannula itself is held steady. The cannula now has no projecting point (see Fig. 2), and may be pushed firmly up the vein to the hilt without danger of piercing the wall of the vein. (4) The syringe, still attached to the inner needle, is completely withdrawn (see Fig. 3), the cannula itself (see Fig. 4) remaining in the vein. (5) The standard adapter on the tubing from the blood reservoir is then firmly attached to the cannula. (6) Two strips of surgical tape are then applied parallel to the cannula and running over its wings, to prevent slipping.

It is not claimed that the instrument is entirely original in its conception. A similar, but narrower, type of cannula, and fitted with a solid stylet instead of with a hollow needle, has long been in use at the Children's Hospital, Birmingham. I have not seen a blunt transfusion cannula with a sharp hollow introducer to which a standard syringe can be attached.

For Withdrawing Blood from a Donor, or for Therapeutic Bleeding

A similar instrument to that described above, but of larger bore (gauge 12 B.W.G.), and having two lateral apertures, has been used. After insertion of the cannula in the manner described above it is attached to a vacuum collecting system.

The cannulae may be obtained from Messrs. Philip Harris and Co., Ltd., of Edmund Street, Birmingham. A spare needle for each instrument is convenient. I thank Mr. J. E. Turner, architect to Hollymoor Hospital, Birmingham, for drawing the illustrations.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 20 1941

RESPONSES OF THE SKIN TO COLD

In this and our preceding issues are published three lectures by Sir Thomas Lewis on some effects of cold on the skin and underlying tissues. It is gratifying to present them to readers of the *British Medical Journal* at the time of the award to the lecturer of the Copley Medal, which is the highest honour within the gift of the Council of the Royal Society. Although many of the phenomena described are of familiar occurrence, and others, such as trench foot and frost-bite, are well known by repute, this is one of the first occasions for a comprehensive account to be presented of the various ways in which cold affects and injures the skin; and no one could be more fitted for this presentation than Lewis, for most of the observations and experiments on which it is based are his own. In his first lecture he tells us how the circulation through the skin is regulated for the varying needs of the body to conserve or lose heat, and how there exist local vasodilator mechanisms for the protection of the more exposed parts of the skin, such as the digits, ears, and nose. These local mechanisms appear to be called into play at temperatures below 15° C., and probably represent a reaction to injury, because at such temperatures other phenomena may be elicited from the skin, such as pain and the local and axon reflex vasodilatation which are common to other injurious agents. In normal skin the injury sustained by exposure to such temperatures has ordinarily no serious consequences, but in certain circumstances one effect of cold may be of much importance. In wound shock there are good reasons for supposing that the chief disturbance is a deficiency in the circulatory blood volume, and it was generally agreed as a result of experience in the war of 1914-18 that exposure to cold was in many instances an important factor in the genesis of shock. Lewis has recently observed that when a hand is exposed to temperatures of 0° to 6° C. for two hours, as much as 60 c.cm. of fluid may be lost into it from the circulation, and he suggests that it is this aspect of the reaction of the skin which may account for the circulatory collapse occurring in those subjected to prolonged exposure to cold.

In his second lecture Lewis deals with three conditions in which exposure to moderate cold produces a more obvious and serious injury of the skin—namely, chilblain, erythrocyanosis, and trench foot. All of these may show histologically those signs of injury which are recognized in other tissues—widening of the vessels, oedema, perivascular infiltration, and destruction of normal tissue. They all occur on prolonged exposure to moderate cold, all present coldness of the skin and high vascular coloration, and all proceed to swelling, blistering, and ulceration; necrosis is most extensive in trench foot, but this can be correlated with the extent

of the exposure. Lewis suggests that these lesions have a common mechanism and that they represent the effects of prolonged cold on the skin and subcutaneous tissues. Chilblains and erythrocyanosis are notoriously prone to develop in those with a "poor circulation"—that is, in those in whom the flow of blood through the skin is persistently slow, and in whom, therefore, the skin and underlying tissues cool most when exposed to low temperatures. The prevention of the two conditions, and of trench foot, lies in ensuring adequate clothing and in the avoidance of any constriction of the extremities.

In his article in the current issue Lewis considers exposure of the skin to temperatures below freezing-point, and we are reminded that the first protection of the skin from freezing is its ability to undergo super-cooling, a property seemingly increased by oiling and decreased by washing the skin. The filth of German prisoners mentioned in recent communiqués from the Russian front may explain why these men are not frozen corpses in the snow. The injury to the skin which occurs when it freezes is to be ascribed to the disruption of the tissues by ice crystals, and the damage inflicted depends largely on the hardness of the frost and its extent. It is pointed out that in many respects the consequences of freezing the skin resemble those of burning or scalding it, and it is suggested that measures which have recently been found to be effective in the treatment of burns and scalds may likewise find their place in frost-bite. With the approach of winter these lectures will provide much material on which those who are treating the ordinary ailments of this country may meditate with advantage; but for those who are concerned with events in the air or on the sea or in lands where frost is severe or prolonged they will be invaluable.

MEDICINE AND AVIATION

The rapid progress in the field of aviation has increased not only the risk of wounds and death by violence among the civil population but also the risk of importation of infectious diseases and diseases spread by insects, particularly mosquitoes. Air Marshal Sir H. E. Whittingham¹ summarized the literature dealing with the relation between the incubation period of infectious diseases and the time taken by air journeys to distant lands; he also drew attention to the administrative measures for sanitary control of air traffic. G. M. Findlay,² in dealing with the present position of yellow fever in Africa, states that the mosquito *Aedes aegypti* and unimmunized men are responsible for the continuation of outbreaks of the disease, for which the incubation period is two to six days, while the individual is infective to mosquitoes for a period varying from four to seven days. With these facts as a foundation Findlay points out how the disease may be spread by the various air lines now in operation. Methods of prevention have also been under investigation, and F. P. Mackie and H. S. Crabtree³ describe how the mosquitoes may be destroyed in an aeroplane by spraying with pyrethrum in a watery base.

¹ *Proc. roy. Soc. Med.*, 1933, 32, 455.

² *Trans. roy. Soc. trop. Med. Hyg.*, 1941, 35, 51.

³ *Lancet*, 1933, 2, 447.

To balance these increased dangers to the health of the civil population by the introduction of the aeroplane, medical aid to certain isolated populations has been made more readily available. Perhaps the most striking example of this is the Australian Aerial Medical Services, which were developed originally by the Australian Inland Mission at Cloncurry under the guidance of the Rev. John Flynn. By 1940 more than 1,000,000 square miles of territory and more than 3,000 scattered and isolated people were under the care of six medical men, who fly in a radius of 400 miles from six different settlements. These areas cover lonely spinifex desert and rocky ranges where, before the introduction of this medical air service, there was little hope for any patient with serious illness or severe injury from accident. All over the world now at short notice patients may be visited by the medical or surgical specialist or be transported to a fully equipped hospital by air ambulance. W. R. Lovelace¹ draws attention to the caution necessary in this respect; all patients with anoxia, circulatory collapse, head injuries, or under treatment with the sulphonamide drugs must be treated by administration of pure oxygen during the flight. In patients with pneumothorax the confined gas will expand as the aeroplane ascends, and pleural adhesions may give way unless the pressure is relieved. In patients with penetrating wounds of the abdomen the gas in the alimentary canal will expand, and there is a risk of the contents escaping into the peritoneal cavity. In these cases, therefore, it is advisable to use an aeroplane fitted with a sealed cabin with the atmosphere therein kept at normal pressure.

Recent researches have also greatly advanced our knowledge of the effects of aviation upon airmen themselves. The tests, collectively known as Flack's tests and originated during the war of 1914-18 by the late Martin Flack while working under Sir Leonard Hill for the Medical Research Committee, now the Medical Research Council, are still in use for the pre-selection of personnel for flying duties, and Air Marshal Whittingham² indicates how these tests have been much expanded and improved. A study of the causes of failure to learn to fly reveals that the factors responsible are poor power of muscle-joint co-ordination, slow reflex action, and emotional changes in a neuropathic group which contains the major proportion of flying failures. The welfare of the successful candidate is continuously cared for by specialists in the medical and research branches of the air forces and air transport companies, special attention being given to the study of fatigue experienced by airmen. Schools of aviation medicine are being rapidly extended for this purpose in many countries; for example, the main School of Aviation Medicine at Randolph Field, Texas, U.S.A., had established some time ago at least eighteen branches throughout the United States, Hawaii, and the Panama Canal Zone. In Great Britain advance has been made in the protection of the eyes and ears of pilots by the introduction of efficient goggles and ear protectors. In some pilots there is deficient hearing in the 4096 cycle area due to cochlear degeneration, but the most serious ear trouble is rupture of the drum during rapid ascent or

descent, owing to the pressures on the two sides of the drum being unequal. H. G. Armstrong and J. W. Heim³ call the resulting condition "aero-otitis media," acute and chronic, for which the method of prevention is to keep the Eustachian tube open by swallowing; the danger is greatest, therefore, in those who may be asleep or unconscious in an aeroplane.

B. Monaco⁴ of Italy agrees with the late Martin Flack that repeated flights at, say, 15,000 feet are harmful and do not help many aviators to acclimatize, and he recommends oxygen at 6,000 feet. H. G. Armstrong⁵ found symptoms of intolerance in American pilots flying not more than three hours a day at an average height of 7,500 to 13,500 feet. H. Strughold⁶ noted a diminution of reflexes—for example, patellar reflex—at 7,500 feet, while M. S. White⁷ observed changes in the electrocardiogram at 5,000 feet, so that oxygen should be breathed before this. On the other hand there is a group of specially selected pilots who do not seem to be adversely affected by repeated flights, including periods of one to three hours at 10,000 to 13,000 feet. Colonel A. D. Tuttle of the United States with three colleagues⁸ studied the physiological and psychological characteristics of a group of 200 successful pilots. They conclude from this selected group that there is more evidence of acclimatization than of deterioration in relation to flying in the senior pilots aged 40 to 47 years still active and with long-service records. These men showed high red cell counts, slow resting pulse rates, low systolic blood pressure, large tidal air volume and vital capacity, slow respiratory rates, and regular breathing; these successful pilots are also very moderate in their consumption of alcohol, and many are total abstainers. It is of interest to recall that A. Keys and his co-workers⁹ found that the relative excellence of acclimatization on high mountains is correlated with a slow pulse, both basal and standing, and a small increase of pulse rate on rising from the prone position.

The physiological effect of acceleration has received much attention in Germany and other countries. There is general agreement that a healthy young adult can tolerate a positive acceleration acting along the vertical axis of the body of 4.5g., or four and a half times the force of gravity, for approximately five seconds; thereafter vision is dim (the so-called "black-out") and consciousness may be entirely lost. The condition is due to a drop in the carotid blood pressure with local cerebral anaemia, and measures to attempt to correct this include inhalation of 5 to 6% carbon dioxide, vasoconstrictor drugs, pneumatic belts, water suits, and flexion of the legs against the abdomen with the body in a crouching position. During ascent in an aeroplane there is evidence that minute bubbles of gas, mainly nitrogen, first appear in the tissues at a pressure corresponding to between 10,000 and 12,000 feet. M. N. Walsh and W. M. Boothby¹⁰ have confirmed Armstrong and Benson's original observation of such bubbles in the

cerebrospinal fluid at this pressure. The condition is similar to that known as "bends" produced in divers during and after decompression, and there is severe pain and possibly collapse. Efforts to prevent the condition in airmen are made by administration of pure oxygen before and throughout the flight, since the nitrogen in the lungs, blood, and tissues tends to diffuse out into the oxygen, but this process is exceedingly slow in some tissues, especially bone marrow. Argyll Campbell and Leonard Hill¹¹ demonstrated that the saturation of bone marrow with nitrogen, and therefore desaturation also, take more than eight hours; thus the breathing of pure oxygen for shorter periods can alleviate the condition of "bends" only to a certain extent.

As oxygen must be breathed continuously at great heights an efficient mask is necessary; in connexion with this J. R. Poppen¹² points out that the ideal mask must be comfortable, and be furnished with a microphone and with valves that do not freeze at -50°C .; further, the oxygen supply must be provided with a mechanism to vary the rate of flow of oxygen as required. The breathing of pure oxygen even from such a mask will help the aviator only up to altitudes of about 32,000 feet, so that to reach greater altitudes with any degree of safety specially sealed suits or cabins must be used in which the pressure may be raised artificially; Group Captain G. S. Marshall¹³ describes such an apparatus. Whatever apparatus there may be in use, if it fails in its purpose at very great heights the only escape for the airman is very rapid descent in his plane or, if outside his plane, without opening his parachute until he reaches an altitude where there is sufficient pressure of oxygen to maintain life. There is a special emergency breathing apparatus for attachment to the aviator which may be used while falling, outside his plane, through space at the lower altitudes. H. Strughold,¹⁴ in a discussion before the Berlin Medical Society, referred to these and other difficulties. Without his parachute open the airman will fall at the rate of 1,000 feet in five and a half seconds; but it is not known how long he can survive at very low oxygen pressure. Further, the rapid change in pressure while falling will increase the risk of rupture of the ear drums. These problems of life at very great heights are still under investigation, and the visitor to the stratosphere may be confronted with other and still graver difficulties than those already known.

DISRUPTIVE WOUNDS FROM HIGH-VELOCITY PROJECTILES

The disruptive or "explosive" effects of small high-velocity missiles are of importance to all who have to deal with them. While there is no sharply defined limit of velocity below which these effects do not occur, they are uncommon at velocities of less than 2,000 ft. per sec. and hence did not attract much attention in the wars of the nineteenth century. But during the war of 1914-18, when muzzle velocities of 2,500 to 3,000 f.p.s. became common, these "explosive" wounds were seen

in large numbers. This gave rise to the belief in several countries that other countries were using explosive or dum-dum bullets, and many such accusations were made, until it became widely known that tissue damage of this sort could arise from any high-velocity projectile. Knowledge of these phenomena is important, not merely that such suspicions should be avoided, but because extensive damage to tissues is common even when both entry and exit wounds are small. It is not uncommon for a considerable zone of tissue round the track of a high-velocity bullet to be pulped as well as infected, and it is said that even as late as 1918 this was not always recognized when the wound was cleansed. Hence insufficient débridement was apt to lead to avoidable gangrene and death. Even now these phenomena are not fully understood, and, because much of the experimental work on the subject is Prussian and difficult of access in this country, further English studies are welcome.

The account given at page 872 of this issue by Black, Burns, and Zuckerman describes the changes in outline produced when a steel ball is fired through small blocks of gelatin. It supplements previous work on gelatin blocks by Colonel L. B. Wilson of the U.S. Army,¹⁵ and the two papers are of especial interest when read in succession. Wilson demonstrated radial penetration of carbon particles round the track of bullets. Zuckerman and his colleagues demonstrate temporary deformations of the gelatin which fully account for such penetration, for radial splits must occur all along the track. A further interesting point in their paper is the fact that the greatest deformation appears after the bullet has left the block of gelatin. This accords well with the observations of the Prussian military workers¹⁶ on the "explosive" disruption of skulls by bullets. They concluded that the skull burst only after the bullet had left it. Although bullets travelling broadside-on can produce disruptive effects of a serious type, it is now recognized that a common cause of the phenomena seen in "explosive wounds" is the kinetic energy of the fluid or semi-fluid particles which are displaced by the bullet in its course. These particles travel both forwards and radially from the bullet track, and by their radial pressure stretch the surrounding tissues to an extent which may be trifling or disastrous according to circumstances. It has been emphasized by Liebert¹⁷ that the damage done to surrounding tissues depends greatly on their elasticity. As muscle is elastic it is usually little damaged; but if the muscles, or their fascial sheaths, are stretched beyond their elastic limit, most extensive tears may appear, as in the 6-inch exit slits sometimes found, without bony fracture, in the legs of men shot when walking or standing.¹⁸ Bone, on the other hand, has little elasticity, and is often fractured at appreciable distances to one side of the bullet track. Large blood vessels are quoted by Wilson¹⁹ as frequently damaged in this way by tearing of the intima, in contrast to the experience of Zuckerman and his colleagues.

We do not know enough yet to make many generalizations on this matter, except the well-known one that empty hollow viscera are little damaged by bullets, while full ones are likely to show very large exit wounds not

only in the stomach, colon, or bladder; the same applies even to tanks containing petrol or water. Further work is desirable, and it is to be hoped that the authors may continue their researches, with, perhaps, the aid of special devices to show the outlines of transient cavities—for example, more illumination or a modern "flash" x-ray unit; or to show scattering and rotational effects—for example, Wilson's charcoal and threads; or, most useful of all, to show the effects of superficial jackets of various degrees of elasticity and tension. It seems probable from the Oxford workers' experiments that the skin is of much value in limiting the disruptive effects from bullets. Would an elastic stocking be of further value in this respect?

GOLD IN THE TREATMENT OF ARTHRITIS

Though the literature on the use of gold salts in the treatment of arthritis is becoming voluminous, it deals almost exclusively with the clinical aspect and the method rests on a purely empirical basis. Freyberg, Block, and Levey¹ have undertaken a research into the metabolism, toxicity, and manner of action of gold in arthritis, and the report on the first stage of their work is of the highest interest and value. Analysis of the amount of gold in the blood and urine after the administration of gold formed the basis of the work, and for this purpose a photo-electric colorimetric micromethod was specifically designed by Block and Buchanan. Gold sodium thiomalate (myocrisin), gold sodium thiosulphate (crisalbin, sanocrysin), and colloidal gold sulphide were the salts used by the intramuscular route, and the last-named was also tested by oral administration. The dosage was recorded in terms of actual gold and not of the particular salt used—a considerable advantage in view of the different proportions in the various forms. Twenty-four-hour collections of urine and samples of venous blood were examined before and after administration of the drug, and in some cases analyses were also made of fluid from the knee-joints. Treatment began with a small dose gradually increased from 10 to 50 mg. of gold and was continued until a total of 500 mg. had been given (equivalent to 1 gramme of myocrisin), the interval between doses being usually seven days. Gold was found in the plasma in increasing amounts as the amount injected rose. After the first dose of 50 mg. had been reached in the fourth week the average plasma content was found to be 0.8 mg. per 100 c.cm. The amount excreted in the urine—found to be the chief route of excretion—increased as larger doses were given, but not in direct proportion. That gold is cumulatively retained in the body was demonstrated by the observation that after an injection of 50 mg. an average of only 1 mg. was excreted daily during the following week up to the time when another injection was due; but the quantity excreted on the day of injection was greater than on the succeeding days. It was further observed that after a full course of up to 500 mg. of gold, equivalent to 1 gramme of myocrisin, significant amounts were found in the blood and urine for a long time after the injections had ceased. In one instance gold was detected in the plasma for thirteen weeks and in the urine for sixteen weeks after completion of the course; similar results were obtained in other cases, and some patients were excreting the metal for several months. Toxic reactions occurred in five out of six patients who took large weekly doses, but none of those whose doses were restricted to 25 mg. of gold had any toxic reactions of moment. The results were similar with

both gold sodium thiomalate and gold sodium thiosulphate, but were much less uniform with the colloidal gold sulphide, whether given intramuscularly or orally. Gold was found in the synovial fluid in equivalent or less amount than in the plasma, and it would appear that differences in this respect may be due to inflammatory changes in the synovial tissues. It was noticed that in some cases an immediate reaction followed injection—apprehension, headache, flushed face, and sometimes a purpuric dermatitis: this reaction appeared to indicate a true drug sensitivity.

Freyberg, Block, and Levey are continuing their investigations in both human beings and animals, and the results are awaited with interest. Their work thus far has thrown much light on the subject, and is of the utmost value as a guide to the safe therapeutic use of gold. There seems to be no doubt that dosage has hitherto been too heavy, and the safe course is to limit it to a maximum of 25 mg. of the metal, which is approximately equivalent to 0.05 gramme of myocrisin or 0.07 gramme of crisalbin, at weekly intervals or longer. It would be worth investigating whether a still smaller dose given for a long time might not yield the best results with less risk of toxic sequels.

REVERSAL OF HALISTERESIS IN THE MAMMALIAN EAR

In otosclerosis there is an area of decalcification or halisteresis surrounding the focus of otosclerotic bone. This area finally becomes, through complete bone resorption, a cavity filled with osteogenetic marrow. In this marrow fresh abnormal bone is formed and the focus of otosclerosis extends. Guggenheim, Gunther, Goodhill, and Irvine¹ state that a series of patients with otosclerosis have been treated with dieting and the administration of dicalcium phosphate, vitamins, insulin, and liver extract and have been kept under observation for four years. These patients have shown no further loss of hearing. The authors suggest that the arrest of further deterioration in the power of hearing is due to the reversal of halisteresis in the otic capsule, with a rebuilding of osseous tissue round the focus of otosclerosis. To test the possibility of effecting a reversal of halisteresis experimentally it was necessary first to produce halisteresis under controlled conditions, and an elaborate research with a variety of drugs, including parathormone and viosterol, was undertaken. As a result ammonium chloride was chosen as the decalcifying agent and white Wistar rats as the experimental animals. It was found that, after decalcification has been produced by the administration of ammonium chloride, the process could be reversed and osseous reconstruction induced by omitting the ammonium chloride from the food and giving a diet high in calcium content. The authors conclude from their observations that clinically it may be possible to inhibit the enlargement of a focus of otosclerosis by giving sufficient amounts of calcium, phosphorus, and vitamins. They explain this inhibition by the reconstruction of capsular bone in the previously decalcifying area around the focus of otosclerosis.

¹ *Arch. Otolaryng.*, Chicago, 1941, 34, 501

H. E. Bierman and R. W. Maxwell (*J. Amer. med. Ass.*, 1941, 117, 1255) record their observations on 117 persons sent to hospital with diphtheritic membranes on the pharynx in whom Manzullo's potassium tellurite test was employed. The test was found to be frequently positive in non-diphtheritic membrane, but was negative only twice. The writers conclude that a negative tellurite reaction, if it contradicts the clinical impression, is not sufficiently reliable to justify abstention from antitoxin.

AN INDUSTRIAL MEDICAL DEPARTMENT

MEMORIAL TO LORD AUSTIN

A new medical department at the Longbridge works of the Austin Motor Company was opened by Air Vice-Marshal Sir David Munro, Chief Medical Officer of the Ministry of Supply, on December 3. The department, which is dedicated to the memory of the late Lord Austin, is a two-story building situated near the main entrance to the works. On the ground floor there is a treatment room for men and another for women, a resuscitation room, and a room for x-ray work and physiotherapy; also a bathroom, primarily for the treatment of serious burns. The x-ray equipment consists of a mobile unit of the latest design and a table fitted with a Potter-Bucky diaphragm and screen attachment. A nurse with experience of radiography is on the staff of the department. The upper floor comprises a large examination room fitted with cubicles, a smaller consulting room, a laboratory for chemical and bacteriological examinations, and offices for members of the medical staff. The furnishing and lighting of the department are on the most modern lines; central heating is provided, and there is a plentiful supply of hot water by means of a calorifier.

The department is intended to provide first-class accommodation for the administrative and technical needs of the three medical officers who have been appointed. Its purpose is to investigate health problems arising in the factory; to provide immediate treatment of major and minor injuries and sickness, and any other treatment which will prevent interference with production and loss of time; to make any necessary medical examinations and give advice; and to facilitate the administrative work required by the many contacts with outside medical practitioners and hospitals. It was emphasized that the work is not intended to encroach on the general practitioner and hospital service of the district, but only to fill in certain gaps in the treatment of persons who have been injured at their work or who are returning after injury or sickness, when some reassessment may be necessary, and generally to help in the discovery and elimination of industrial causes of ill-health by research into occupational disease and by propaganda and other measures.

A Policy of Health Care

This is only the latest development of the policy of health care followed by this company since it began in a small way thirty-five years ago. For twenty years it has retained the services of nurses, of whom latterly twenty have been employed at ten ambulance stations, dealing on the average with 460 cases, slight or more serious, every day, this on an employment roll which now numbers between 25,000 and 30,000.

In opening the building Sir David Munro said that it was not entirely philanthropy which had led the management to start this kind of work. It had been shown to be a paying proposition to have constant supervision by doctors and nurses who understood the occupations in which the workers were engaged. In his view unless the works doctor was part and parcel of the management he was not, in Sir David Munro's own words, "getting his stuff across." Mr. Murphy, chairman of the Works Hospital and Benevolent Fund, mentioned that during the years 1933-40 the workpeople had paid to the Birmingham Hospital Saturday Fund nearly £69,000, to which the company had added £13,000, making £82,000 in all. Vouchers had been issued amounting to £66,000, and thousands of cases had been sent to convalescent homes. Dr. Donald Stewart, chief medical officer, and Drs. N. T. Glynn and G. N. J. Thomas, medical officers, also took part in the proceedings. The very large company, which included the chairman and several members of the Association of Industrial Medical Officers, representatives of the local profession and hospitals, and in which Dr. H. Guy Dain (Chairman of the Representative Body) and Dr. S. Wand (Chairman of the Birmingham Branch) represented the British Medical Association, then inspected the department.

HOME GUARD CASUALTIES

ARRANGEMENTS FOR ACTIVE MILITARY OPERATIONS

At an interview at the War Office representatives of the medical press were afforded some information about the arrangements for treating Home Guard casualties in the event of invasion. Where the Home Guard operates in conjunction with Regular troops the R.A.M.C. units accompanying the latter will deal so far as possible with Home Guard casualties. If there are no such units in the vicinity arrangements will be made in advance between Home Guard medical officers and medical officers of health for casualty collection, conveyance, and treatment.

The movements of Home Guard casualties will normally be from the scene of action to the appropriate Home Guard aid post, stretcher cases being carried by Home Guard stretcher bearers; and from the aid post to the appropriate E.M.S. hospital (stretcher cases) or civil defence aid post (other cases) in civil defence ambulances and sitting-case cars respectively. The general principle is that the responsibility of the Home Guard will continue up to and include their own aid posts, and will comprise the provision of field-dressing facilities; but when once the casualties have been received by the civil defence casualty organization the responsibility for their care will devolve on the latter.

Home Guard aid posts will be established only where there are no civil defence first-aid posts or points reasonably adequate for dealing with casualties and sufficiently near the probable scene of action to be reached by the stretcher bearers. The aid posts should be accessible to civil defence ambulances and so sited as to fit into a comprehensive network of civil defence as well as Home Guard services. In certain districts, where E.M.S. hospitals or civil defence aid posts are considered too remote from the probable scene of action, regimental aid posts may be necessary with a medical officer in attendance, and the transfer of casualties from these aid posts will be the responsibility of the civil defence or military authorities, whichever is nearer. Stress was laid upon the need for keeping to a minimum the number of such posts in the interests of economy in man-power and equipment. It is not intended that mobile first-aid posts shall operate at the scene of action or at Home Guard posts, but it may be necessary to send them to the assistance of a civil defence aid post which is subjected to pressure owing to the reception of Home Guard casualties.

Use of Civil Practitioners

The fact that Home Guard or regimental aid posts may require the continuous attendance of a doctor or rota of doctors must be taken into account in the schemes of medical officers of health for utilizing civilian practitioners in acute emergency. But in other cases it is not intended that in an emergency Home Guard medical officers shall be liable to be mustered for full-time duty. Their main responsibilities are to train stretcher bearers, organize company or platoon aid posts, advise commanding officers on medical matters, and ensure proper co-ordination with civil defence services. They will be available to be called on for duty at hospital or aid post (fixed or mobile) where reinforcements of normal medical staff may be needed, and where, in fact, casualties from their own Home Guard units may be received for treatment.

The arrangements were described as an interlocking of civil and military medical resources, with a pooling, as necessary, of personnel, hospitals, equipment, and transport. It was also stated that ambulance trains would be "stabled" at strategic points throughout the country and be used as much as possible. The mobile first-aid posts are intended for civil "incidents," but they are, of course, hidden reserves. The first-aid machinery of the Home Guard is independent of the mobile units, but the latter will be sent wherever the need is greatest in the event of acute emergency.

- According to *Tubercle* the mortality from pulmonary tuberculosis in Wales fell during the forty years of this century by 49.3%. The fall occurred fairly evenly except during the war years 1914-18, when a rapid rise took place.

Reports of Societies

EFFECTS ON KIDNEY OF LIMB COMPRESSION

The meeting of the Section of Surgery of the Royal Society of Medicine on December 3 was devoted to a discussion on the effects on the kidney of trauma to parts other than the urinary tract, with particular reference to crush or compression syndrome.

Mr. E. ROCK CARLING, president of the Section, said that so far the war had furnished few new surgical problems, but one outstanding observation had been the association of grave and often fatal damage to the kidneys after prolonged compression of the limbs. It was impossible to believe that a similar syndrome had not been associated with injuries in civil practice—mine accidents, for example—but it had not been observed, or at any rate recorded. Very little on this subject had appeared in English literature. The researches of Bywaters and others had revealed in German periodicals references to similar cases occurring in the last war.

Discussion of Pathogenesis

Dr. E. G. L. BYWATERS proposed a classification of types of excretory failure seen after trauma wherein the functional change observed in shock and dehydration (oliguria, azotaemia, and casts) was separated from more specifically renal damage such as that seen in crush injury, after burns, after trauma to the liver, and possibly in some types of obstetric shock. He gave an account of the clinical, biochemical, and pathological features of crush injury, and laid emphasis on the renal tubular necrosis and muscle necrosis seen post mortem. In the light of these findings he discussed the pathogenesis, in particular the role of myohaemoglobinuria, muscle necrosis, and secondary oligaemic shock. A similar picture was seen after muscle ischaemia due, not to prolonged crushing, but to vasospasm or rupture of main vessels. It resembled in many respects the condition following mismatched transfusion and the much rarer condition of paralytic myohaemoglobinuria.

Prognosis depended on many factors. The duration of the crush did not seem to bear much relation to survival. Those crushed for a long time might recover. Another factor influencing prognosis was the extent of the injury. Particular care should be exercised in the case of muscle damage near the trunk which was not very obvious clinically. A further factor was the rise of blood urea. In the severe recovered cases there was a fall in the blood urea at about the same time as death occurred in the fatal cases. But the blood urea could rise to very high levels, and the patient might recover without any treatment whatever. Recovery occurred in about one-third of the cases admitted; in about two-thirds death took place from renal failure, generally at about the fifth to the eighth day.

Mr. R. BEESEY spoke of the surgical aspect of the treatment of cases, and attempted to define the problem from the surgeon's point of view. In the crushed limb the changes observed included necrosis of muscle, of patchy distribution; haemorrhage into muscle, but not constant; oedema of limb; and increased tension of tissues within the fascial compartments of the limb. Intense arterial spasm appeared to be a common cause of ischaemia. Clinically, peripheral arterial pulsation was sometimes absent when the case was first seen. Loss of nerve function was recorded in the majority of cases.

Little in the way of operative treatment had been employed as yet, and probably quite rightly. Primary amputation of the limb had been tried in a few cases and decompression of the limb by incision in a few. The two aims of saving the patient's life and saving the patient's limb might be mutually antagonistic in that restoration of circulation in the crushed limb might lead to a sudden flooding of the body with myohaemoglobin or toxins. He described five cases admitted to St. Thomas's. In none of the published case reports was there evidence that palliative surgical treatment had played any part in saving life. The case for amputation remained unproved. Limb decompression as a means of saving the limb was indicated in cases where peripheral pulsation had completely disappeared. Splintage and refrigeration of the damaged limb with ice packs

as a method of reducing metabolism during the period of ischaemia and possible toxic production appeared to be rational if begun early. He pleaded for more objective study of the pathology of the syndrome.

Approach to a Rational Therapy

Dr. J. McMICHAEL said that, considering that a year ago they were quite mystified by this condition, he thought it could be claimed that some good progress had been made. There seemed little doubt that breakdown of autolytic products from dead or dying muscle was the main factor which damaged the kidneys. Two main effects were produced in the kidney after muscle ischaemia: some chemical substance was liberated which poisoned the tubule cells, and there was also a tubular blockage factor, quite possibly resulting from the precipitation of myohaemoglobin casts in the tubules. With these points in mind it was possible to make an approach to rational therapy. The kidney must be thought of from the beginning in people who had sustained crush injuries. The mistake had been made of waiting until about the third day, when renal damage was already manifest and severe, before treating the renal condition. It should be impressed on rescue parties that the real danger to people pinned down by the limbs under wreckage was kidney failure, and therefore it was of paramount importance to ensure a good diuresis, particularly at about the time when they were due to be released from the pressure, and every effort should be made by means of abundant warm drinks to ensure a good urinary flow. The advantages of good diuresis would be dilution of chemical substances within the kidney tubules and perhaps prevention of precipitation of myohaemoglobin casts.

Once the victim was released the circulation was likely to be flooded with toxic products, and therefore it was necessary to institute a more rational way of dealing with that situation. Dr. McMichael did not think any severe additional damage or difficulty would be created by the immediate application of the tourniquet. It should be applied to the limb proximal to the site of crushing, and when the patient reached hospital it was desirable that the circulation through the limb should be restored only when the people responsible for the patient's welfare were satisfied that a good diuresis was established. The gradual release of the circulation might be attempted by replacing the tourniquet with the sphygmomanometer cuff and slowly deflating. It was possible that in these cases the limb vessels were already in spasm, so that little might be achieved by such measures. Another expedient might be to pack the limb in ice so as simultaneously to reduce the blood flow through the limb and to diminish the rate of tissue breakdown, dependent on the action of the enzymes, which acted best at about body temperature.

The next point was alkalization of the patient's blood or urine, because these patients tended to have a low alkali reserve. Administration of alkali in quantities adequate to make the urine alkaline was a rational procedure. Sodium bicarbonate and sodium citrate should be given by mouth from an early stage in quantities of 200 to 300 grains a day. The use of the sodium salt must be emphasized because the high blood potassium present in these patients might conceivably be one of the biochemical factors leading to death. Good case records were available showing improvement in urine output after extensive alkaline therapy. Good diuresis, of course, could not be maintained in the presence of circulatory collapse, and shock should be treated by transfusion, the transfusion fluid being serum or plasma. These suggestions were merely tentative in the present state of knowledge.

Defining the Clinical Problem

Mr. D. H. PATEY said that his attention was drawn to the problem by the case of a woman admitted to hospital after being in a bombed house, where a heavy beam had rested across her thighs for some hours. She recovered from shock; twenty-four hours later blood in the urine was noticed, and in spite of measures taken to deal with renal damage she passed less urine. and at the end of a week died with renal suppression. That case was something with which they were not at that time familiar. It was thought at first that there was direct injury to the kidney, but that was disproved post mortem. The solution of the problem lay much deeper.

The biochemical and histological factors must be left to experts in those subjects. The surgeon's duty was to define the clinical problem. In the first place, these cases were not clinically "crush syndrome," but "compression syndrome." The people had been pinned under wreckage for hours, and the limbs had been compressed, not necessarily crushed. When the beam, or whatever it might be, was removed, there was often no crushing of the limb, but there was a great amount of oedema. This was a new syndrome because the factors leading to its development—the collapse of buildings imprisoning people—were substantially new. Apart from the complete syndrome going on to renal failure from the fifth to the eighth day, there must be many lesser cases, with no fatal termination, but these were unrecognized because the appropriate biochemical investigation had not been carried out.

In some of the correspondence in the medical journals a policy of "healthy neglect" was urged. Experience had proved to him that such a policy was unsound. All cases admitted with compression syndrome were potentially extremely serious, and at the beginning the serious could not be distinguished from the comparatively minor case. The renal lesion was regarded as the effect of some toxin produced at the compression site as a result of direct muscle trauma or ischaemia. This toxin got into the circulation and in some way damaged the kidney. But that conception had been quite sterile therapeutically, and therefore he suggested another conception—namely, that the renal damage was not due to toxins from the compressed limb, but to the passage of something from the circulation into the compressed limb, so that if one could restore the fluid and what it contained from the compressed limb to the circulation at the earliest possible moment there would be a better chance of helping these patients. So far there had been opportunity to treat only one or two patients on this hypothesis. The idea was to apply an intermittent positive pressure in the lower part of the limb with the object of mechanically reducing the oedema. Instead of treating these patients by putting on a tourniquet at the time of the accident, he thought there was a case, purely as an experimental clinical procedure, for giving them intermittent positive pressure treatment. Immediately the patient was released from the compression a firm crêpe bandage should be put on, and when admitted to hospital the oedematous limb should be treated vigorously by the action of a pressure pump or massage or gravity with the object of restoring back into the circulation the fluids which had escaped into the limb. The only case he described which had been so treated would, he believed, have recovered in any event, but in his view the rate of recovery was hastened.

The Nature of the Lesion

Prof. SHAW DUNN spoke of the importance of establishing the nature of the lesion and the constancy of its occurrence. Symptoms pointing to the existence of renal lesion were oliguria and rise of blood urea, and in many cases some early haematuria. There was always the question of the effectiveness of casts as a means of reducing total kidney function, but lack of concentration of urea corresponded with damage of kidney epithelium as the cause, not with cast blockage. He showed microscopical sections illustrating damage to tubules. It seemed as if something passed through the general circulation, injuring only the kidney, simply because the kidney was the organ which could concentrate substances to a greater extent than any other. Dilution was one of the main expedients in protecting kidney tubules from damage.

Mr. V. H. RIDDELL said that on admission of a large number of casualties to hospital it was very easy to miss an early crush syndrome unless the examination was systematic. The patient might look well and be temporarily passed over. The only way to avoid mistakes was to examine each patient in turn. In crush syndrome the localized erythema of the skin would draw attention to the lesion. Not only crush syndrome but other injuries, including possibly operative shock, might also be associated with depression of kidney function, varying from a temporary anuria to fatal suppression of urine.

Experience of Cases

Several speakers described cases within their recent experience. Major MAGNER (Canadian A.M.C.) reported crush syn-

drome after a motor accident. Mr. WILLIAMSON mentioned two cases of renal failure several days after compound fracture of the femur. Dr. ROSCOE CLARK showed a recovered case in which no one would have suspected renal involvement had not certain investigations been carried out. Mr. GRAHAM, to "add confusion to a subject already confused," described a case, not of compression for some hours, but only for a few minutes, which was followed by oedema of the limb above and below the site of injury and oliguria and other renal symptoms.

Mr. GUY BLACKBURN said that the term "healthy neglect" had been used, in contradistinction, he assumed, to "continuous interference." He believed "healthy neglect" to be an unsound policy in dealing with this newly described syndrome. Had he not been fortunate enough to see a patient at the very week-end on which Mr. Bywaters's article appeared in the *British Medical Journal* the patient might not have been so lucky in the final outcome. He believed chemotherapy to be strongly contraindicated in these cases. In some cases it had been tried as a prophylactic, but it had achieved nothing, and in a case in which he used it the man recovered in spite of sulphanilamide. Many reports also stated that patients had been catheterized, perhaps more than once. In a number of air-raid casualties with extrarenal damage and oliguria there was difficulty in passing water; this was not a simple anuria, but anuria combined with inability to urinate. Many recovered within forty-eight hours, but he had seen patients catheterized over several days. The institution of a tidal drain on the first or second day of treatment, after enough urine had been obtained for pathological investigation, would have saved inconvenience as well as the risk of infection by repeated catheterization.

Dr. BYWATERS, in reply, mentioned the need for observation of a large number of these cases if treatment was to be assessed. The Medical Research Council was doing valuable work in collecting cases; he hoped that those who had cases interesting enough to publish would publish them quickly, and, if not sufficiently interesting, would at least see that they were recorded in some way.

PLANNED WARTIME NUTRITION

At the Royal Institution on November 25 Prof. J. C. DRUMMOND, scientific adviser to the Ministry of Food, gave the first of a series of lectures on planned wartime nutrition. This first lecture was a review of the progress of the last twenty years, particularly pointing the contrast between the position in the last war and the present.

Prof. Drummond reminded his audience that during the last war food problems did not assume great importance until well on in 1917, when the German submarine campaign began to make itself felt. Until then there were few restrictions. Had the deterioration in the quality of food which became evident during the latter part of 1917 and continued into 1919 begun at the outbreak of the last war, and been progressive from 1914 onwards, the state of health and the general condition of the population at the cessation of hostilities might have given cause for alarm. Looking back on that period in the light of present-day knowledge it was possible to say that there had been a tendency to deterioration. It was not unreasonable to claim that the nation passed through the last war on an application of nutritional knowledge to which there had not been many additions during the previous fifty years. In the latter part of the last war there were a few scattered references to vitamins, and guarded references to the importance of something which to-day was fully recognized. The late Prof. Starling, for example, stated that there was obviously something in fruit juice which was important from the point of view of health, and which was not to be found included in any of the three units—protein, fat, and carbohydrate—which at that time were considered to comprise the whole of the elements of diet. The nutrition of the population during the last war was not considered from the point of view of vitamin deficiency. By 1918 there was evidence of progressive deficiencies which, had they continued, would have had far-reaching effects on the health of the nation.

All this threw into more striking relief the remarkable advances in nutrition since 1918. He spoke in particular of the advance in respect of the vitamin B group. There were, obviously, many parts of the skein to be unravelled even yet. It was by no means certain that yeast extract or an extract of wheat germ, which was very rich in vitamin B, could be replaced, so far as the vitamin B complex was concerned, by the synthetic vitamin. Some factors had evidently not yet been identified—indeed, there might be as many undiscovered as had so far come to light. The position was still fluid, still on the verge of further elucidation. He mentioned this as explaining why there had been reluctance to depend on any other than natural foods. However well the mixture of synthetic vitamins or isolated elements was combined to replace natural foodstuffs, there was always at the back of the mind the fear that some essential factors as yet unidentified might be left out. It seemed, therefore, that the major problems of feeding the nation in wartime had to be solved, so far as that was possible, by the provision of natural foodstuffs.

Just before the outbreak of the present war the knowledge of nutrition had advanced from the laboratory and clinical study to the field of practical and social economy, aided by surveys carried out by Sir John Orr and others. The League of Nations set up inquiries regarding nutrition in practically all the countries in the world, and much the same picture was presented in every centre. There were among the peoples of Western Europe certain clear-cut food deficiencies—in nearly every case deficiencies of the principal vitamins. Thanks to all this work it had been possible during this war to make fairly good estimates of the nutrients required by the various groups of the population so that their health might be maintained during a period of expected restriction in food supplies.

Prof. Drummond said that in his following lecture he would show the basis of the calculations made with a view to drawing up a planned nutritional policy for the nation in wartime.

LOUSE-BORNE TYPHUS FEVER

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on November 28, with Dr. E. H. R. HARRIES in the chair, a paper was read by Dr. MELVILLE D. MACKENZIE on "Some Practical Considerations in the Control of Louse-borne Typhus Fever in Great Britain in the Light of Experience in Russia, Poland, Rumania, and China."

Dr. Mackenzie said that louse-borne typhus fever was an acute infectious disease, lasting from twelve to sixteen days, characterized by continuous temperature, generalized rash (absent from the face), severe toxæmia, and marked nervous manifestations.* It spread with extreme rapidity through a badly nourished population, and the epidemic form was closely associated with famine and overcrowding. Another factor of great importance was widespread movements of military or civil populations bringing non-immunes into a district where the disease was endemic. Overcrowding alone was not sufficient to cause epidemics in an endemic area. Only in so far as it increased the numbers of lice and the facilities for their transmission did overcrowding play a part. As for climatic conditions, louse-borne typhus disease was a disease of cold countries and was unknown in tropical regions, although it might occur in mountainous sections of the Tropics. The endemic form occurred in the early months of the year, and the complete cessation of cases after June and July was striking; the epidemic form occurred at any time of the year. In epidemics the death rate varied widely, from 20 to 70%, depending on such factors as the age of the population at risk. It was rare for an individual to have a second attack. Adults coming into an endemic area got the disease more severely than those of similar age already living in endemic regions. The population in endemic areas might be partially immunized by a mild form of typhus.

* A memorandum on louse-borne typhus, by the Ministry of Health, was summarized in the *Journal* of December 6 at page 817.

Some Clinical Aspects

In the strenuous conditions under which extensive typhus epidemics occurred the individual, already weakened by cold and exposure, failed to notice the initial symptoms of the disease, so absorbed was he in the struggle for food, clothing, and warmth. The first sign might be mental confusion or delirium. In the great majority of cases acute delirium was established only at the end of the first week. Two very constant symptoms at the onset were headache (frontal or occipital) and bronchitis. Clinical diagnosis was often difficult. Two reliable clinical signs were complete absence of rash from the face and the fact that the rash did not appear in crops. The deeper the colour of the rash, the greater its abundance, and the earlier its appearance, the more serious was the prognosis. The delusions tended to be of a terrifying character, with nightmare dreams. Dissociation delusions were often characteristic of cases in the second week of the disease. For example, a patient would ask for his chin to be taken off for shaving, or his legs to be hung up in the wardrobe. At the time of convalescence the patient's mental condition was often far from normal. A disconcerting symptom might be the recurrence of transient delusions in the convalescent stage. A persistent symptom during convalescence was slight tremor of the hands and localized paralysis.

Measures of Control

Personnel dealing with a widespread epidemic should be protected by the use of special clothing; portable baths and showers should be taken on transport, with as good rations as it was possible to obtain. Disinfesting stations should be set up where refugees entered a territory. Experience in Russia and other countries had demonstrated the great danger to which personnel working among typhus patients were exposed and the need for the most careful supervision of their activities by the medical officer in charge. The most dangerous work was in the admission block of the hospital and in the removal of bedding. In view of the lower mortality at earlier ages, only young personnel should be employed. No vaccination as yet had been shown to protect workers under field conditions. Hair should be cut short and, if possible, shaved, including hair on the body. Protective clothing should not be worn for two or three hours without change. Opinion was divided on the question of wearing masks, but they should certainly be worn in conditions in which there was liable to be disturbance of dust. When it was necessary to sleep in squalid peasants' houses or in infested railway trains a special type of sleeping bag of closely woven material was used. This was 10 ft. long, turned at the end, and drawn up from the inside with a circular tape.

The incubation period might be twelve to fourteen days, and after this there might be four or five days before the rash appeared. Infection was very liable to occur among frequenters of public markets. A point of practical importance was the rapid wane of an outbreak when nutritional conditions improved. In addition to destruction of lice, all nits should be dealt with, so that patients should undergo a second disinfestation a week after admission to hospital. Soft soap mixed with paraffin was sufficient if conscientiously applied with the nail brush after the patient had been shaved. When disinfestation of bedding and clothing of patient and immediate contacts was complete the cleansing of the ambulance, disinfesting station, and personnel must not be overlooked. Immediately typhus occurred all practitioners should be kept informed of the existence and extent of the disease in their locality, and a brief description of the important diagnostic signs should be circulated. In the period 1901-26, 87 groups of cases occurred in Glasgow, and in 36 of these the diagnosis of the primary case was missed.

Laboratory Aspects

Dr. G. W. M. FINDLAY discussed certain laboratory aspects of typhus. It was essential to isolate the rickettsia virus, and this could be done by taking blood from the patient and inoculating it into guinea-pigs and rats. It was at first thought that blood must be taken during the first week of the fever, but actually it was possible to obtain rickettsiae very much longer.

If whole blood were inoculated into guinea-pigs and rats after the seventh or eighth day no reaction or a delayed one might be obtained, but if the blood were allowed to clot and the serum taken off a reaction could be obtained. The rickettsia could sometimes be isolated throughout the febrile period and also during the whole of convalescence. In the Balkans it had been found that there were people apparently in perfect health from whom it was possible to isolate the rickettsia, although they had never shown any symptoms of the disease. There were numerous other tests. Biopsy was at one time favoured, but that had been given up now in ordinary typhus. Recently an intradermal test in the rabbit had been worked out. Serological diagnosis chiefly resolved itself into the Weil-Felix reaction, which usually became positive at the end of the first week. An important point in this method was to show that there was a progressive increase in the titre. There was some relation between the severity of the disease and the highest maximum titre reached, but, on the other hand, there might be very low reaction in cases of typhus.

No drug treatment was employed in typhus with success. The sulphonamides were entirely without action on human typhus. The use of immune serum had been suggested, but the majority of observers had found it useless; that was the experience in Spain last spring. More promising results had been obtained with hyperimmune serum, either from horses or rabbits. As to the response of rickettsia apart from the louse, in the tissues rickettsiae were not very resistant. They were destroyed almost instantaneously at a temperature of 100° C. A very large number of vaccines had been attempted, but at present it must be admitted that the attitude on vaccine prophylaxis against this disease must be pessimistic.

Prof. P. A. BUXTON raised the question of the risk of typhus in this country. If some person came over in an aeroplane from Lisbon and went down with typhus it would result in only a primary case so long as the surrounding community were free from lice. In a clean community, with adequate facilities for washing of the person and, at frequent intervals, washing of underclothes, the body louse could not exist. The body louse was common at present in the tramp community, and he thought it was also more common than was generally suspected in labour camps, among men employed in building jobs and the like, where washing facilities might be small. On the subject of head lice, K. Mellanby had collected statistics obtained in fever hospitals in all the big cities of the country which showed that in schoolgirls in cities infestation was as high as 50%, among boys it was never quite so high, while among adolescents the rate remained high in girls but fell away among boys. Opportunities had recently arisen of collecting large bodies of fact with regard to young women going into certain types of employment, and the results were consistent with Mellanby's figures. It was known that there were many cities and industrial areas in this country where the rate among girls and young women was not far short of 50%. The relation of the head louse to typhus fever was not known; but the head louse could not be satisfactorily distinguished from the body louse. Entomologists would say that the head louse and the body louse were very closely related, that they interbred and produced fertile offspring. In considering the transmission of typhus the safe line to take would be to suppose that the head louse might be dangerous, though perhaps not as dangerous as the body louse.

Dr. A. FELIX could not agree with Dr. Findlay's pessimistic view of typhus vaccination. He believed that more recent methods of growing rickettsia in the tissues of animals would shortly yield successful methods of prophylaxis.

Corrigendum

Our attention has been drawn to an error in condensation of the reported remarks of Group Captain Dalziel Dickson in the Section of Laryngology in the *Journal* of November 22 (p. 744). He was reported to have said that the "regional specialist" supervised all researches in so far as they concerned his specialty and that he or his deputy visited every hospital centre. The officer to whom Group Captain Dickson was referring was not the "regional specialist" but the "R.A.F. consultant in the specialty at the Central Medical Establishment in London."

Correspondence

"Crush Syndrome" in Obstetrics

SIR,—Since E. G. L. Bywaters and D. Beall published their account of the crush syndrome in this *Journal* (March 22, 1941, p. 427) we have studied two cases in the obstetric department of the British Postgraduate Medical School in which an apparently similar condition followed the trauma of labour. The first was a woman who, after a difficult labour lasting twenty-three hours, rallied from severe shock only to die eight days later with renal failure, the blood urea reaching 388 mg. per 100 c.cm. before death. The chief histological lesions were found in the kidney and resembled those described by Bywaters and Beall—namely, marked tubular degeneration with "haematogenous casts" in the tubules. In the second case, after a difficult labour lasting fifty-eight hours, marked oliguria developed with a blood-urea reading of 79 mg. per 100 c.cm. There was no shock, the lowest blood pressure being 136/88. Recovery was rapid.

These cases suggest the existence of an apparently hitherto unrecognized clinical entity in obstetric practice. The conditions leading to its development being such as can in general only rarely occur in any one maternity hospital, this letter is written in the hope that the collection of an adequate group of fully investigated cases in different centres may throw light on such questions as incidence, genesis, clinical pathology, and morbid anatomy. A further question which calls for concerted study is the new light which the crush syndrome may throw on the hitherto baffling problem of "obstetric shock," in which trauma of the soft pelvic tissues has long been known to play an important part. The view of some obstetricians that obstetric shock is due to the flooding of the circulation with toxic elements elaborated in the crushed tissues adds further relevance to this question.

The Medical Research Council subcommittee which has been set up to co-ordinate research on the "crush syndrome" would be glad to receive any data which are available. They would also keep investigators informed of the progress of work in this field. Brief records may be sent to Dr. A. N. Drury, Medical Research Council, London School of Hygiene, Keppel Street, W.C.1.—We are, etc.,

JAMES YOUNG.

JOHN MCMICHAEL.

British Postgraduate Medical School,
London, W.12, Dec. 5.

Sulphonamides for Ophthalmia Neonatorum

SIR.—Dr. W. J. Clancy says (November 22, p. 749) that the treatment of ophthalmia neonatorum has been "greatly simplified" by the sulphonamide group of drugs. I do not think that it can be too strongly emphasized that since the introduction of these drugs the treatment of ophthalmia neonatorum has been revolutionized. It is now of little importance to investigate the bacteriology of the condition, and I am in complete agreement with Dr. Clancy regarding the relative unimportance of local treatment.

The routine treatment I use now is to give 0.125 gramme of sulphapyridine with each feed hour-hourly for 48 hours and then discontinue. I do not consider that continuing treatment after this time is of any value. By now the oedema will have gone, the discharge almost ceased, and the eyes be on a fair way to full recovery. Local treatment merely consists in frequent swabbing away of mucus and the instillation of an oily drop.

As I have never seen sulphapyridine when used in this way cause any complications, and have never known the condition resistant to this treatment, it is my teaching in the Rotunda Hospital that failure to administer the sulphonamide group of drugs immediately ophthalmia neonatorum is recognized amounts to criminal negligence.—I am, etc.,

Dublin, Nov. 28.

L. B. SOMERVILLE-LARGE.

Combined Active and Passive Immunization against Diphtheria

SIR.—In the second of the very interesting articles on combined active and passive immunization against diphtheria (November 29, p. 759) figures were given showing conversion

rates of 97%, 97.7%, and 96.5% in three groups of persons immunized with monthly spaced doses of 0.1 c.cm. and 0.3 c.cm. A.P.T., in addition to antitoxin. These results may be misleading unless it is realized that the groups from whom they were obtained were closed or semi-closed communities with recent exposure to diphtheria infection and were of persons who, it is reasonable to assume, had already had priming doses such that almost any subsequent dose of antigen would render them Schick-negative, and that these results are not what may legitimately be expected from similar doses used on the general child population.

This question of dosage is not that with which these articles are primarily concerned—the authors do in fact suggest two doses of 0.3 c.cm. even in closed communities—and the point is only raised because those results may be quoted as evidence in support of the procedure recommended by the Ministry of Health to give two doses of A.P.T., 0.1 c.cm. and 0.3 c.cm., which has already been shown by Dr. Bousfield and others to be unsatisfactory at least and may prove to be disastrous.—I am, etc.,

Wimbledon Common, Dec. 4.

G. HIGHFIELD-JONES.

The Stimulant Action of Iron

SIR.—There are many problems in connexion with the use of iron by the body still awaiting solution, and the writer of the annotation under the above heading (November 29, p. 176) has perhaps over-simplified the problem of fitting together existing knowledge. If one practical effect of his article is to discourage the wide use of iron as a prophylactic for infants the price to the country will be much illness which could have been prevented and a consequent loss of woman-power in the war effort. The haemoglobin level of babies in this country, whether breast-fed or bottle-fed, varies within very wide limits, and their average level is such that their resistance to infection is less than that of babies with a higher haemoglobin level—a higher level that can be maintained by giving prophylactic iron treatment from, say, 2 months to 12 months of age. That is, I think, fully established, and the Ministry of Health, on the advice of its Advisory Committee on Nutrition, circularized all maternity and child welfare authorities in 1932 (Circular 1290) urging that prophylaxis on these lines was needed. Because infants are very prone to anaemia we need not conclude either that a low haemoglobin level is normal or that infancy is a "morbid state." But let us not quibble over definitions of normal, but get on with the job of using the means available for safeguarding the health of small children in these days when exposure to infection is increased by war nurseries and shelters. I hope someone else will take up the cudgels on behalf of anaemic women.—I am, etc.,

London, N.W.3, Dec. 6.

HELEN M. M. MACKAY.

Nutritive Value of Bread

SIR.—Following Dr. Harriette Chick's letter (November 29, p. 790), I regret that in my paper on the nutritive value of bread (November 15, p. 689) I referred to the wholemeal flour used by her as of 82% extraction, but Dr. Chick's paper does not specifically state that the flour used was of 100% extraction. In view of the Accessory Food Factors Committee's recommendation quoted in the first paragraph of the paper and the evident application of the work to human diets, in which wholemeal bread very rarely indeed consists of the entire grain—some 5% of the coarsest bran being practically always removed—I assumed that the flour used was of the 82% extraction in general use at that time.

In reply to several inquiries I have received about the yeast which I used, this was moist baker's yeast. A further experiment on similar lines to the one recorded has lately been completed without the use of yeast. The dietary constituents in this case were mixed with water, steamed, and fed in a firm doughy consistency. This further experiment gave results confirming those recorded in my paper.—I am, etc.,

London, W.6 Dec 5

M. D. WRIGHT

Rest for Civil Defence Workers

SIR.—May I draw the attention of your readers to facilities that are open to civil defence workers through the Civil Defence Workers Rest Department of the Joint War Organization.

Accommodation is available in three Joint War Organization convalescent homes near London (which have been temporarily allocated for this purpose) to civil defence workers of both sexes in the Metropolitan area and Outer Ring who are in need of change after illness or injury, or of rest and recuperation as a result of a prolonged spell of duty, etc. There is no charge to applicants, who may apply on their own account or through their A.R.P. authority, in which case applicants are asked to attend the weekly Red Cross medical inspection, bringing a certificate from their own doctor and a leave permit from their A.R.P. authority.

In the case of civil defence workers who have been hospital patients (either in- or out-patients), these may proceed direct on application by the lady almoner to the Civil Defence Workers Rest Department. In addition to full-time civil defence workers, the facilities are at present also open to part-time A.R.P. personnel, registered fire-watchers injured on duty, and those who have been discharged from the service but who contracted their illness or injury while in the service. Free transport from Central London is provided.

Accommodation is also available in the Bristol area for local personnel, and it is hoped shortly to extend to other parts of the country. All applications and requests for further information should be made to the secretary, Convalescent Section, 6, Cadogan Square, London, S.W.1 (Slo. 9951).—I am, etc.,

HORDER,

Chairman, Civil Defence Workers
Rest Dept., J.W.O.

London, S.W.1, Dec. 7.

Industrial Medical Boards

SIR.—A very strong case has been made out for the establishment of Boards for the assessment of industrial fitness of both men and women. I venture to propose the following plan:

1. At every Labour Exchange the services of an advisory medical officer (with special industrial experience) should be available. He would undertake a preliminary "weeding out" of workers in order that grossly unsuitable allocations of man- and woman-power may be avoided in the future.

2. Every Regional National Service Officer should be provided with the services of an Advisory Fitness or Medical Board consisting of three medical members with special industrial experience, one of these to be appointed by the Ministry of Labour, another by trade union representatives, and a third by employers' organizations.

3. In cases of special difficulty or an appeal all three members of the Board should examine and report on the worker to the N.S.O. for the region.

4. Part-time and not whole-time appointments should be made both to the Boards and in the local areas. The work would be much too difficult and exacting for whole-time employment. The standard of the work done would inevitably decline after a certain period of whole-time employment.

5. Right of appeal should be granted from the local assessor to the Board either by the worker or his employer.

6. The function of the local and regional services would be to advise upon fitness for actual or proposed employment at the time of a first allocation (a) to an industrial employment, or (b) for special industrial training, or (c) after an appeal by a worker for a change of work on medical grounds.

7. Appellants should be required or encouraged to bring with them letters or certificates from their own personal practitioners, and from the works doctor (if any).

In any event a radical and immediate change in the present procedures is clearly needed.—I am, etc.,

Worcester, Dec. 6

HOWARD E. COLLIER.

Industrial Medical Services

SIR.—Dr. Donald Stewart, in his comprehensive article on industrial medical services in Great Britain (November 29, p. 762), seems to imply that factory doctors and surgeries are the outcome of the last war. True, the movement for the appointment of factory medical officers and nurses received a great impetus as a result of experience gained during 1914-18, as did the industrial welfare movement generally, but a number of British firms had well-developed schemes long before that.

I am speaking now of doctors engaged entirely in looking after employees while at work, examining new entrants, attending accident cases, supervising general factory conditions, and

so forth, and not those employed by firms, friendly societies, and sick clubs to attend employees and their families in their homes. For instance, Cadbury Brothers Ltd. appointed their first whole-time medical officer in 1902, and had a whole-time nurse or nurses before that. There may be firms who had doctors and/or nurses at an even earlier date, but I am fairly certain that between then and 1914 other industrial concerns adopted similar measures.—I am, etc.,

Birmingham, Dec. 9.

J. A. BROWN.

Medical Supervision of Industrial Workers

SIR.—In the *Journal* of November 29 (p. 783) there is a summary of the B.M.A. *Report of Committee on Industrial Health in Factories*. According to the report of the duties of an industrial medical officer, the first duty is "medical supervision of employees during working hours." Does this mean that the medical officer is to supervise the manner in which the employees are using their bodies while doing their work, or simply to supervise the conditions under which they are doing their work? If it is the first, it is pertinent to ask how many medical officers have been trained to look at the human machine in use as an engineer is trained to look at his machine in action. Because unless he has been so trained, and is able to detect and correct wrong body use in standing, sitting, walking, lifting, bending—in fact, in every action in which he uses his body in his work—he is failing entirely in his supervision, as the special human machine he should supervise is subject to the same laws as the mechanical machine, and disabilities, defects, exhaustion, and premature wearing-out arise as surely in the one as in the other from wrong use.

It cannot be questioned that one of the most important functions of a supervisor is to see that the worker, as he works, is conserving the efficiency of all his vital organs while enabling him to perform every necessary action, no matter how arduous or complicated, with ease and economy of effort. But the science of the correct use of the body as a unit—using all its parts (voluntary and involuntary) at one and the same time for a common end—has not been explored by physiologists or clinicians. It is an unknown subject to the profession and therefore to industrial medical officers. This indictment is substantiated by the numbers of cases we are called upon to treat for which no cause can be found, but in every one of which there are certain to be found evidences of maladjustment of posture and a consequent wrong use of the body. Until this gap in our medical knowledge and practice is filled, so long will our workers (brain as well as manual) suffer unnecessarily in health and efficiency, whatever else we do for them.—I am, etc.,

Bexhill-on-Sea, Dec. 4.

A. MURDOCH, M.B., C.M.

Health of T.N.T. Workers

SIR.—Perhaps a few notes from one who had a good deal to do with T.N.T. in shell-filling factories during the last war may be useful to those now undertaking the special work of industrial physicians in charge of modern factories.

1. I found, first, that it was highly necessary to "vet" medical certificates given to workers at my factories, since apparently the mere fact that some T.N.T. work was done there sufficed for a diagnosis of T.N.T. poisoning and for a certificate to be signed accordingly by doctors who had never been inside such a factory; nor would the latter trouble to inquire of the medical officer-in-charge whether the patient was, or had recently been, working with T.N.T. before making such a diagnosis. Fewer than half the number of persons attached to the factories actually worked with T.N.T.—for instance, those concerned with the cleaning and painting of empty shells, or with stoking or driving engines bringing the raw material to the works, had no contact with it. There were, alas! certain blatantly wrong diagnoses, which could not possibly have been made had the patient been examined and his statement alone not been accepted as true. Fear of poisoning certainly was an element in disorders of T.N.T. workers.

2. In order to keep down risk of T.N.T. poisoning it is necessary to examine every worker on admission to the works and exclude certain types. If the M.O. will consider the lesions liable to be produced by T.N.T. or similar poisoning, he can easily make a list of those he should exclude *a priori*—for

instance, since renal trouble may be caused it is advisable to exclude all multiparae who have had albuminuria of pregnancy; persons with gastro-intestinal trouble suggesting ulceration or colitis, or a history of jaundice; cases of heart trouble with suspicion of the presence of a bacterial or toxic poisoning of the heart muscle; anaemias of any sort (by pigmentary test, confirmed, if needful, by blood count).

3. The mere bluishness of the lips is not of primary importance if it clears up after, say, an interval for a meal. Hundreds of those who entered the canteen with blue lips due to excessive "fumes" left the canteen with normal-coloured lips. The remedy is, of course, plenty of ventilation and thorough cleanliness from T.N.T. of the whole factory.

4. The idea held by Prof. Benjamin Moore (who worked at one of my factories for several weeks and whom I knew then) that the main source of penetration of T.N.T. was through the skin is, in my experience of large numbers of T.N.T. workers and their lesions, not established. The mouth and nose are the main ways in. Here are a few facts for digestion.

At one of the earliest filling factories there were some forty men on experimental plant, working long hours, covered with powder containing T.N.T., and, probably, often sleeping in their clothes. Again, there were over thirty women whose job it was to clean shell-caps from amatol, which had been used to cap the shell while in transit in the factory. These women cleaned the caps in troughs filled with paraffin, at the bottom of which was a sludge of ammonium nitrate, while the liquid was apparently a saturated solution of T.N.T. They had all worked for three months or more at this job. No single one out of these two groups had any form of T.N.T. poisoning, though if T.N.T. actually penetrated the skin surely both groups should have at least given a positive Webster test in the urine (carefully taken). None of the whole group of women tested by my colleague and by me, save one case in which there appeared to have been slight contamination, showed the "T.N.T. reaction" in the urine; possibly absence of a + test would seem to indicate retention of T.N.T., but, of course, could also indicate that T.N.T. had not penetrated the skin. This work was done in a shed where there was no other T.N.T. work done, so the latter is the more probable explanation. Again, I examined about sixty stomach contents: all contained T.N.T.; girls commonly licked their lips. Mouth-breathers showed T.N.T. in the saliva; nose-breathers showed definitely less at the posterior part of the airway than in the front of the nostril—indicating that the nose acts as a partial filter.

So it follows that T.N.T. must not reach the mouth and nose; the air of the factory should be clean and dust containing the poison must be avoided.

5. Alternation of labour—fourteen days on T.N.T. processes and fourteen elsewhere—is a great help, and when a worker otherwise symptomless has the slightly glassy eye suggestive of poisoning, although the urine is negative, it is wise to order transference to some part of the works where there is no T.N.T. for a period varying with the case. Pay should be the same, or else the "patient" will think he is being victimized. The cases in which one may reasonably suspect commencing jaundice are those with definitely "too yellow" serum (the first place to look for signs of commencing jaundice); a few drops of blood from the finger or ear allowed to clot in a small tube with narrowed ends and examined later as to colour of serum against white paper are all that is needed. Constipation may also cause "too yellow" serum; but as this may be a symptom of early poisoning "non-T.N.T." work should be ordered in any such event.

6. As to rashes, there appeared to be two types: one, probably allergic, like a very severe urticaria on exposed parts (I got mine within twenty-four hours of starting work); and another, eczematous type, much rarer and apparently occurring mainly in men who were accustomed to daily beer in quantity (there was only one woman with this rash), though other alcoholic drinks made the condition, when established, promptly worse. Incidentally, I do not remember a single case of toxic jaundice in a person who had a strong "acute" skin reaction, though this needs checking.

7. From experience and correspondence with the head of a firm manufacturing T.N.T. I formed the opinion that what we called T.N.T. poisoning was due not to pure T.N.T. (crystals,

originally white, but soon becoming yellowish), but to various by-products, mainly unsaturated nitrations of the toluene. The material supplied to us at first in more or less crystalline form contained a treacly stuff which stained the skin yellow or brown, or even black, and which, as evidenced by the effects on a certain research chemist, was the main offender in the poisoning. Later on we had a somewhat branny form in bags, but by that time poisoning had largely disappeared.

It is to be hoped that the lesson of cleanliness of the works, air, and personnel and the value of alternation of labour in and out of T.N.T. processes have been remembered.—I am, etc.,

Birmingham, Nov. 30.

H. G. P. CASTELLAIN.

Encopresis in Children

SIR,—Dr. Charles Burns is to be congratulated upon drawing attention to the unusual but distressing symptom of faecal incontinence in childhood (November 29, p. 767), which, as he says, receives but scant mention in textbooks of paediatrics. In my experience such cases fall into three distinct groups: (1) those in which there is a delay in the establishment of complete bowel control even up to 13 or 14 years of age; (2) those in which normal control is established in infancy but the symptom presents itself in childhood or adolescence; (3) those in which the major symptom is not faecal incontinence but the tendency to play with the faeces or deposit the motion, either parcelled or otherwise, in unusual places such as pocket, drawer, cupboard, etc.

In cases in the first group the condition is closely allied to, and often associated with, enuresis, and occurs in children who are constitutionally of nervous, excitable disposition, and weak in sphincter control. The condition tends to improve as the child grows, the symptom often disappearing with some chance change of circumstance, such as admission to hospital for observation, change of residence, removal to a new area, etc. The second group, of which Dr. Burns's first, second, and fifth cases are examples, comprises cases of neurosis in which the symptom expresses, as he says, "a protest against an inimical and threatening environment; an unconscious reaction, both of aggression and of fear." These, I agree, require observation at play (play therapy) in the case of young children, so that the basis of the neurosis may be determined, while in the case of older children and adolescents psychiatric interviews are indicated. The third group, of which Dr. Burns's third and fourth cases are examples, presents a much more serious problem, usually of deep psychological significance. These cases are commonly associated with other symptoms such as purposeless stealing and collecting of oddments, pilfering and hoarding of food, wilful destruction, lying, and secrecy. In my own experience, the children in this category invariably realize that they are unwanted. Two outstanding examples are those of an illegitimate boy of average intelligence and considerable pluck who was fostered in a home for babies until he was 13 years of age, and an illegitimate boy, adopted at 3 years of age, who had presented the above-described behaviour difficulties for some years, but developed the interest in faeces when at 13 years of age he learnt for the first time of his adoption. Following psychiatric investigation, these cases usually require some drastic alteration in their environmental circumstances before adjustment can be brought about.—I am, etc.,

Liverpool, Dec. 8.

MURIEL BARTON HALL.

"Wound Phagedaena"

SIR.—The report of two interesting cases of "wound phagedaena" by Mr. Alexander Callam and Mr. Alexander Duff (December 6, p. 801) illustrates some of the difficulties in the treatment of the condition. Although, as they suggest, wide excision is the correct treatment, this may prove a formidable undertaking when the affected area is extensive. In two such cases I have incised the normal skin beyond the inflamed margin with the diathermy knife—the incision extending down to muscle—forming a narrow trench around the lesion. In both cases this procedure was successful in arresting the spread, and subsequent healing of the areas resulted.—I am, etc.,

Central Middlesex Hospital, N.W. 10, Dec. 8.

T. G. I. JAMES.

Endocrine Therapy of Hypertrichosis and Acne

SIR,—In the report of Dr. A. P. Cawadias's Thomas Vicary Lecture on hermaphroditism, in your issue of December 6 (p. 818), the lecturer is quoted as having said: "I know of no fact more capable of increasing our faith in internal medicine than the complete transformation of repulsively feminized boys into normal virile adolescents, thanks to a few hormonal injections, or the change into beautiful and complete womanhood of girls with hairy faces and bodies and thick and acne-ridden skin, thanks to oestrogenic hormone therapy."

Dr. Cawadias was referring presumably to intersexual cases only. To avoid disappointment to many sufferers from hypertrichosis and acne vulgaris, I think it should be made clear that it has been pretty thoroughly established that no form of hormone therapy is the slightest use in ordinary cases of either hypertrichosis or acne vulgaris. For many years I have at intervals consulted authorities on endocrinology as to whether any hormone had yet been isolated which would cure hypertrichosis in a woman, and have always received a negative reply. All my experience and reading lead me to a similar conclusion with regard to acne vulgaris.

If Dr. Cawadias can give references to any work which will justify an alteration in these views I at least shall be grateful.—I am, etc.,

London, W.1, Dec. 9.

A. C. ROXBURGH.

"Ether Convulsions"

SIR,—Ether convulsions have often been mentioned in your columns, but as they are predominantly due to heat the experience of an anaesthetist in the Tropics may be of interest to your readers.

In the summer here in Punjab the outside temperature goes up to about 120° F. As most of the Indian hospital theatres are not equipped with air-conditioning systems, fans and "khaskhas tatties" sprayed with water serve to cool the temperature. I have observed ether convulsions when the thermometer in the theatre registered 90° to 105° F. as dry and 80° to 90° F. as wet temperature. They were seen in some septic cases, those with fever, generalized peritonitis, and in prolonged cases when the peritoneum was about to be sutured. This last fact shows the convulsion to be due to saturation of the system with ether or to an overdose. But I have also seen convulsions within a few minutes of induction in cases of high fever with generalized peritonitis. Most of the patients were children and young adults; none was in old age. During the last four years only three patients have had severe convulsions. Over sixty others have had only twitchings or spasms, and these were prevented from developing into convulsions by the following treatment.

As soon as twitchings and spasms in the face muscles or the orbicularis palpebrarum or finger muscles are noticed the head is kept raised about 8 inches and ice put over it and on both sides of the neck and over the region of the medulla. Firm pressure is maintained over both carotid arteries for three seconds, and repeated once or twice. I had often noticed the convulsions in cases where the head of the table was kept low, and as the raising of the head relieved them I am convinced that brain congestion of the Rolandic area is an important cause of these attacks. The prolonged inhalation of vapour after bubbling of much oxygen through an inferior make of ether or old-standing ether has caused convulsions. In these cases there was no cyanosis, but often there is a trace of cyanosis in ether convulsions. Typical ether convulsions begin from above downwards, face, fingers, etc., and are different from the tremors or twitchings sometimes seen in the extremities if they are not well supported. Ether convulsions never begin in the lower limbs.

As diminution of serum calcium and alkalosis, due to quick elimination of CO₂, and consequent interference with normal respiratory quotient, are contributory causes of the convulsions, calcium gluconate 10% given intravenously at the first appearance of the twitchings is beneficial. If the patient's colour is pink, showing hyperoxygenation, due to oxygen being allowed continuously, only CO₂ is administered, but if there is cyanosis or even slight duskeness both CO₂ and oxygen are given. A

clear air-way is maintained and any tenacious mucus in the throat is removed. Sodium evipan or pentothal was not injected, because, in addition to the above treatment, withdrawal of the mask and careful early change to chloroform and ether mixture and then to chloroform controlled the convulsions, and the operation was continued; later increasing doses of fresh open ether without oxygen were allowed until the operation was completed. Evipan, in my opinion, is contraindicated in weak patients with low blood pressure and when the head is raised, because it brings about a further fall in blood pressure.—I am, etc.,

K. E. MADAN, M.D., D.A., D.O.M.S.
Senior Anaesthetist, Mayo Hospital

Lahore, Oct. 16.

Post-war Medicine

SIR.—Dr. A. Piney (November 22, p. 753) calls for an answer to the question, What is wrong with medicine to-day? In the same issue (p. 753) a science master of Manchester Grammar School makes the disquieting disclosure that in his experience candidates for the medical profession are very frequently inferior, both intellectually and culturally, to those who propose to adopt other professions. Are we correct in deducing from this that medicine at present fails to attract the best brains? The question naturally arises. Why should this be so? In seeking an answer to the first question it is possible that we may obtain an answer, in part at least, to the second.

It would be a difficult matter to answer Dr. Piney's question within the necessary limits of a letter in your columns. It is easier to set out briefly what one hopes might be achieved if the profession were to become organized in a definite service, thus indicating by implication some of the things which some of us think are wrong with medicine to-day.

The problem in its essentials boils down to being largely a matter of finance. On the one hand, the patient cannot at present afford to be doctored as we think he ought to be, while on the other hand the doctors have not the means to provide by themselves the ideal service. The maintenance of good health and the cure and alleviation of ill-health should therefore become a charge on the community generally and not a burden to be borne by those individuals who are so unfortunate as to become ill and those others who happen to be charitably disposed. I have attempted to make out my case in the form of parallel columns, thus:

THE ADVANTAGES OF AN ORGANIZED MEDICAL SERVICE

To the Public

1. Relief from the financial burdens imposed by illness, often crippling in their effects.
2. Ready access to everything required in the diagnosis and treatment of disease.
3. It would be possible to encourage the maintenance of good health in the community generally by education and the provision of the means for living a healthy life.

To the Medical Profession

1. Relief from the financial strain of setting up in practice. At present the would-be consultant has to face long years of struggle before anything like an adequate return comes his way. The general practitioner's opportunities are more often than not determined by the amount of money he can find than by his academic and postgraduate successes and experience.
2. More regular hours of work, more time to study his cases, more leisure to keep physically and mentally fit, greater opportunity for postgraduate study.
3. A regular income with freedom from the worry of trying to collect money owing for work done.
4. A pension to retire on at a reasonable age, thus opening the way for younger men.
5. The chance of promotion for those keen enough and capable of working to get out of the groove which most of us get into the day we start in practice.
6. Relief from the necessity, for purely business reasons, of living in large houses.

In conclusion, it may be said that the State has already taken over the responsibility for so much which was previously within

the province of the family doctor that it will soon be impossible for most of us to make a living from that form of practice. It looks, therefore, as though—whether we like it or not—we shall be driven into some form of organized service.—I am, etc.,

Bridlington, Dec. 3.

C. J. GORDON TAYLOR, D.M.Oxon.

X Rays in Treatment of Inflammations

SIR.—The Council of the Medical Defence Union desires to endorse in general the views expressed by Dr. H. Courtney Gage in his letter in the *Journal* of December 6 (p. 823).

The records of the transactions of the Union clearly show that there are many hidden and some obvious dangers associated with the use of radiotherapy by medical practitioners who have not had special training and experience in the vagaries and technicalities of x-ray administration. The Council of the Union desires immediately to protest most strongly against the employment of x rays in the treatment of inflammatory and allied conditions by casualty medical officers and other practitioners who have only a limited experience in the use of the apparatus necessarily involved, since it is felt that if this practice is encouraged and extended consequential and grievous injuries will be sustained by patients, leading in time to claims for damages upon the medical practitioners responsible for the treatment.—I am, etc.,

R. FORBES,

Dec. 8.

Secretary, Medical Defence Union.

Administration of Voluntary Hospitals

SIR.—The academic and professional status of the voluntary hospitals is unquestioned, and their popularity with patients is deservedly great. They owe this to the whole-hearted and free co-operation (mark this word) of their medical staffs. These staffs are in a healthy sociological state because free debate, free criticism, and free initiative as regards improvement of each and every department exist.

There is no room or necessity for reversion to the primitive schoolmaster-schoolboy tradition inherent in the medical superintendent type of regime. Such a superintendent is bound to be inferior intellectually to some of his professionally more able staff, and unless he is a man of very exceptional character the result will be friction and the hospital will suffer.

If the committee system has proved itself to be an efficient mode of internal medical government in the teaching hospitals, responsible, of course, to the lay board, what is the point of regressing to a less democratic, more Hitlerian, form of organization? I had thought that the maintenance and the development of democratic principles was the chief cause for which the war is being fought. The staffs of the voluntary hospitals, and their representatives upon post-war planning committees, must insist that a reactionary step be not forced upon them. If maintenance of hospitals financially by the State is to follow the war, why should not the hospital staffs be as answerable to, and as responsible to, the State as they now are to their lay boards? But since hospital organization upon the lay side, and in those matters lying between the practice of medicine and details of maintenance, is becoming more and more of a specialty, I suggest that an "organizer" be appointed to medical staffs, that he be on an equal footing with, and not on a superior footing to, his practising colleagues, that his time be devoted to the details of administration, and that he shall sit both on the medical and on the lay committees, as others of his colleagues do. He and they will thus both learn much from each other.

There is a final point. Civil Servants dare not act on their own initiative, and this produces the type of mind which seeks to do as little as possible so as to avoid doing wrong or irritating superiors. The tempo of the Civil Service is thus that of the snail. Delegation of responsibility to trustworthy committees or bodies is the only cure for this bureaucratic katatonia.

The stage is thus obviously set for a real experiment for the improvement of administrative efficiency. Is there any reason why the opportunity should not be seized? If it is to be seized, pressure must be put by the members of the voluntary hospital staffs upon their accredited representatives.—I am, etc.,

London, W.1, Dec. 10.

GEOFFREY BOURNE.

Voluntary Hospitals

SIR,—I have been presented by a doctor on our hospital committee with the opportunity of perusing correspondence in your *Journal* resulting from Sir Frederick Menzies's timely, pertinent, and provocative query relating to voluntary and municipal hospital systems.

To me as a layman the letters published have been illuminating and instructive, but as treasurer of our local hospital I was disappointed that with only one exception was finance referred to, though I realize mercenary considerations might perforce only have been generalized in the "pros and cons" of the varying professional arguments put forward. Your correspondent Dr. Wilfred Shaw (November 8, p. 665), in dealing with post-war medicine, however, raises its importance as a factor, and generally I agree with his conclusions, in particular that voluntary hospitals must in time become aided either directly by the State or by the municipalities, though I trust with the minimum of control, which, if unavoidable, should be on a variable scale according to the degree of pecuniary assistance granted to meet the individual needs. It is only right that those hospitals, some perhaps being well endowed and/or having conserved their resources, should continue to control their policies, management, and direction, assisted by State or municipal representation on the Management Board according to the monetary services rendered, from which it naturally follows that the less fortunate would be the more assisted by such representation.

The difficulties will not be insurmountable provided a policy of give-and-take and the right atmosphere are in evidence when the whole matter is dealt with.—I am, etc.,

Walmer, Nov. 26.

C. W. LANGDON.

Increase of Tuberculosis

SIR,—If Prof. Lyle Cummins (November 29, p. 787) considers that I have misrepresented the theory offered in his first letter (November 1, p. 632) I offer him my apologies, though I do not think that reference to his letter would convince any impartial person that the misrepresentation was serious. The discharge of tuberculous persons from sanatoria certainly figured prominently in his theory, and I seized upon this as the only element capable of any sort of statistical examination, however approximate.

But we need not waste time discussing the finer points of interpretation of the theory, for the question at issue is really quite clear. To put it in its proper terms, I think it is fair to say that Prof. Lyle Cummins maintained that the increase of tuberculosis morbidity and mortality observed in this country during the present war is due to changes in the conditions of spread of infection brought about by the war. I said that there was little evidence for this belief. Prof. Lyle Cummins has offered none. Further, I quoted some facts which, I think, do constitute evidence that in the similar increase observed during the last war nutritional factors played an important part. It is, of course, possible that the causes operating in this war are entirely different from those operating in the last, but there is certainly no evidence which would justify this assumption.

Prof. Lyle Cummins is correct in assuming that I do not deny that "clinically evident tuberculosis" is due, in the first place, to infection. I would go even further and agree that all forms of tuberculosis, whether clinically evident or not, are due, in the first place, to infection. This, however, is irrelevant. We are discussing what factors determine whether tuberculosis is of the clinically evident variety or not, and, in particular, what is responsible for the increase in the incidence of the clinically evident variety observed in wartime. Prof. Lyle Cummins emphasizes the importance of presumed changes in the conditions of spread of infection, and asks: "Is it necessary to postulate anything else?" I think many would agree that his question has to be answered in the affirmative.—I am, etc.,

London, E.1, Nov. 29

A. L. JACOBS. M.R.C.P.

A Human Ostrich

SIR,—In connexion with Dr. J. W. McK. Nicholl's letter in your issue of December 6 (p. 827), headed "A Human Ostrich," the following case reported by Dr. Philip H. Wheeler (in the *New England Journal of Medicine*, January 9, 1941, p. 57) of a

mental patient in Battleboro, Vermont, seems worth a note in your columns.

The patient was a man of 43 years who complained of abdominal pain, and x rays revealed the presence of foreign bodies which he had swallowed. At operation there were removed: 69 narrow staples, 24 wide staples, 21 pieces of glass, 73 miscellaneous articles including open safety-pins, hairpins, corroded needles, ordinary pins, tin-tacks, pieces of safety razor blades, one piece of hacksaw blade, and a screw—187 articles in all.

Five years later the patient was again operated upon for abdominal pain and removal of foreign bodies. This time there were removed: 440 pieces of glass and 277 metallic bodies—wire, needles, nails, pins, a bottle cap, and fragments of a barbed-wire fence—717 articles in all.

The following year he had to undergo a third operation for the same reason, and there were removed 425 articles—wire, pins, toothpaste tubes, glass fragments, tacks, etc. Altogether at the three operations there were 1,329 articles removed.—I am, etc.,

Bureau of Hygiene and Tropical Diseases,
London, W.C.1, Dec. 9.

H. HAROLD SCOTT.

Obituary

ROBERT A. WELSH, M.B., B.S.

Dr. Robert A. Welsh, a greatly respected member of the medical profession in Northumberland and a familiar figure at many Annual Meetings of the B.M.A., died on November 21, a few days before his seventy-seventh birthday. On his retirement in March, 1939, after nearly fifty years' service as a general practitioner in the Felton area, he received an illuminated address, a book containing the names of several hundred subscribers, and a cheque, in the presence of a large number of old patients, neighbours, and medical colleagues, some of whom travelled long distances to show their esteem and affection for Dr. Welsh.

Robert Anthony Welsh was born on December 3, 1864, and had his medical training at Newcastle-upon-Tyne, graduating M.B., B.S. of Durham University in 1891. After a post at the Northumberland County Asylum, and some experience of practice in a mining district and two large towns, he went to Felton and succeeded to the practice of Dr. Hedley, whose daughter he married. His unselfish and devoted work among rich and poor, to which his old friend Prof. Grey Turner pays tribute below, was rewarded by the love of all his patients. He joined the British Medical Association as far back as 1893, and represented the Newcastle Division at nearly all the Annual Representative Meetings from 1920 to 1937. He was also a well-known attendant at the Panel Conferences, and served for several years on the Rural Practitioners Subcommittee of the Insurance Acts Committee. He seldom spoke from the platform, but followed closely the proceedings of the Representative Body, and much enjoyed meeting old friends during this annual break in an arduous professional life. Robert Welsh was a diligent reader of the *British Medical Journal*, and had a great affection and admiration for its late Editor, Sir Dawson Williams, with whom he kept in touch for many years. In 1933 he wrote for the *Lancet's* series "The Doctor's Day" an interesting article, "In the Depths of the Country," vividly describing the work of a single-handed practitioner in a Northumbrian village. The article ended: "No other type of practitioner is so tied up and unable to get help from a colleague. However, as we make our bed, so we must lie on it, and the life has its charms; and had I my time to begin again I would still be a country doctor. But there is only a certain type of man cut out for the job."

Prof. G. GREY TURNER writes:

I should like to send a note of appreciation about my old friend Robert Anthony Welsh of Felton, Northumberland. He was always known as "Welsh of Felton," and one can

scarcely realize that for the last three years he had lived in retirement near Newcastle-upon-Tyne. Practically the whole of his professional life was spent in country practice, and he was a model of what a country doctor should be. The appreciation of his numerous friends was shown by the presentation made to him when he left Felton after serving the community faithfully and well for no less than forty-seven years. It was characteristic of this country doctor, who was really modest and shy, that in thanking his friends he said he accepted the gifts not only as a recognition of his own services but as "a compliment and tribute to the medical profession." It will be a grief to many that he has not been spared to enjoy the leisure so well earned. But he missed the happy associations which his practice provided, and he was deeply affected by yet another war in which several members of his family are serving.

Welsh took the deepest interest in his patients from every point of view, and their sorrows especially were of deep concern to him. As a result he came to know the life-history of most of the families within a wide range of his home, and as he had a most retentive memory it was very interesting to hear him detail the circumstances of their life-history that might have a bearing on their ailments. Welsh was a good clinician, and not only on the medical side, for he belonged to a day when the country doctor had to deal with his own accidents at all events, and his results in fractures and other injuries were wonderfully good. His interest in the profession generally was very deep, and by steady reading he kept himself well informed of everything that concerned the welfare of his patients. Though he often disagreed with modern tendencies he was always prepared to discuss the relative merits of the various methods of treatment and was most anxious that his patients should have all the advantages available. Among his patients his word was law, for he "managed" rather than merely "treated" them, and in a wonderfully tactful way. He was very fond of literature, especially biography and poetry, and he could quote accurately from many of his favourite authors. In the same way he retained a vivid recollection of the sayings of many of his old teachers, and these he would often recall. He was proud of the old Medical College in Newcastle-upon-Tyne and of the University of Durham, of which he was a graduate. Though he hated ostentation he liked to wear his academic dress on suitable occasions. Welsh was an outstanding letter-writer, and would certainly have shone in the heyday of that art. His well-known clear, legible hand will be sadly missed by his correspondents. When he sent a patient into hospital or for consultation the case was always accompanied by an explanatory letter, and there can have been few points of importance that he ever missed. I cherish a large number of his communications not only for the sake of the vivid word-picture of clinical conditions but for their detail of the circumstances generally associated with the doctor's work and their shrewd comments on men and affairs. He had an intimate knowledge of all that appertained to the country, and was a keen gardener. In his later days it was most interesting to hear him recall the routine of country life long years ago. I frequently urged him to write about these things, for I felt sure that some day there would be readers intensely interested in the vivid account which Welsh was able to give of the life in and about the large country houses with which he was familiar. He was a devoted member of the B.M.A., and regularly attended meetings, not only locally but the Annual Meetings, and it was always a delight to see him among his friends on these occasions. His attitude to many of the happenings in the profession was critical and often sceptical, but he was absolutely straightforward and honest and could not tolerate sham in any form.

Of course, for many years he belonged to the "horsey days," and one of my earliest memories is of seeing him set out from Newcastle on the box seat of a closed carriage with a spanking pair of horses, so that he could be in attendance on one of his patients recently operated upon, who was carefully packed up inside on her long journey of nearly thirty miles to her home in the country. In later years I have known him much put to keep his engagements when the weather was bad, and I vividly recall an occasion in the depths of winter when he made the journey to Newcastle riding uncomfortably on a milk float in order to be present at an early morning operation on one of his patients. He never got over the wrench

of leaving his old home and his old friends among his patients, but it was a keen satisfaction to him that one of his sons was able to succeed him in the practice, which had been in his wife's family for five generations. The house in which he lived has been a doctor's residence for over 200 years. He was devoted to his family, and of recent years his few holidays were spent in visiting among them.

ELWIN NASH, M.R.C.P., D.P.H.

We regret to announce the death of Dr. Elwin H. T. Nash, lately medical officer of health for Heston and Isleworth, which took place on November 28.

Dr. Nash, who was born in 1872, received his training in Manchester, where he was Public Health Research Fellow, and at St. Thomas's Hospital, London. He qualified in 1896, and took the D.P.H. in 1908. After serving as resident house-physician at St. Thomas's he entered the public health service. Among the appointments he had held were those of senior assistant medical officer for Derby and medical officer of health and school medical officer for the borough of Wimbledon. Later, and until his retirement, he occupied the same positions in the newly formed borough of Heston and Isleworth in Middlesex, one of the towns on the growing edge of London, with a population in 1931 of 75,000. Here, in a new area and with a sympathetic authority, he was able to put into practice many ideas with regard to maternity and child welfare, children's nutrition, school dentistry, and diphtheria immunization.

Early in the thirties he instituted what was probably the first school orthodontic clinic in the country, having been impressed, as he said, not only with the physical disadvantage of the large numbers of children who suffered from dental disfigurements, but by the real inferiority complex which such disfigurements created. His method of persuading those in his charge to undergo diphtheria immunization showed him to be a first-rate organizer and propagandist, and his reward was in the relatively high percentage of his school population so immunized. He had also his own strong views on school feeding and on nutrition in general, and *Dr. Nash's Cookery Book* found a wide acceptance. On such subjects as school lighting and the ideal class-room he was an expert, and he served on central committees dealing with those and other subjects. He was in fact the ideal school medical officer, and no circumstance which could possibly affect the health of the school child was too small to interest him.

For many years Dr. Nash occupied various positions of responsibility in the Society of Medical Officers of Health. He had been president of its Home Counties Division and of its Maternity and Child Welfare Group, and eventually became a very successful president of the society itself. He also "passed the chair" of the Medical Officers of Schools Association, and served that body in many capacities.

In the British Medical Association, which he joined immediately on his qualification, he did some excellent divisional and central work. He served as representative at twelve Annual Representative Meetings, and was never content to be a silent one. He was chairman of his own Division, South Middlesex, in 1929-31, and at the Annual Meeting in Belfast in 1937 he was vice-president of the Section of Hygiene and Public Health. He served on many committees at headquarters, including the Insurance Acts, Public Health, and General Practice Committees, and here again he was no lay figure, but took an active part in much detailed subcommittee work.

Behind his burly form and forceful manner was a man with the kindest of hearts, a high sense of public duty, and abilities out of the common. He had been happily married for over forty years, and his wife survives him.

Dr. ALFRED COX writes:

The above obituary notice shows what an active and versatile man Nash was, but it does not allude to one episode in his career which deserves honourable mention, for it was something of which he was justly proud. He was one of the pioneers (there must be few now living) who took part, as a representative of Accrington, in the memorable Manchester Conference of May, 1900, at which was begun the movement which resulted

in a complete revolution in the constitution and future outlook of our Association. It was there I first met him and began a greatly valued friendship. He followed this up by active work in his own locality in the difficult period when the new Divisions were being formed. Indeed, he was one of the most enthusiastic B.M.A. men I have ever met, combining with his enthusiasm knowledge and idealism in a rare degree. Whenever the Association asked for service that was within his range (and his range was a very wide one) he gave it fully and gladly. He was particularly knowledgeable and useful on committees dealing with school medicine. He was one of the all too few men in the public health service who had a real understanding of and sympathy with the general practitioner's point of view. The practitioners in his own area showed that they realized this by sending him with unfailing regularity to the Representative Body. Among his many interests was the Public Medical Service movement, which he heartily supported. I can sincerely endorse all that has been said above of his personal qualities. He leaves behind him in the hearts of his friends a memory of a loyal and lovable man who was a devoted worker in the best interests of his profession.

Dr. ALFRED F. HEALD of Dulwich, assistant medical secretary of the London Panel Committee, died at Goring-on-Thames on November 21 at the age of 77. He was born at Burnham Beeches and educated at Hurstpierpoint and Fitzwilliam Hall, Cambridge. He became a pharmaceutical chemist, but after a few years took up medicine and qualified from St. Mary's Hospital in 1903 as L.S.A. He settled in Peckham, where he carried on a large practice. Joining the London Panel Committee in 1916, his knowledge of pharmacy was of particular value when the London Insurance Pharmacopoeia was being compiled. Later he became a member of the National Formulary Subcommittee of the B.M.A., and also served on the Minister of Health's Advisory Committee on the Definition of Drugs. During his membership of the Panel Committee Dr. Heald occupied the chair of the Pharmacy Subcommittee from 1918 to 1919, and acted as treasurer from 1925 to 1930, when he was appointed organizing and assistant medical secretary to the Panel Committee, in which capacity he rendered valuable service to the insurance profession in London. His fine presence, combined with a genial disposition and sound common sense, contributed to the esteem in which he was held, and his passing will be a great loss to his colleagues both on the Panel Committee and in the county. His health showed signs of failing in 1939, when he suffered from coronary thrombosis. The intensive bombing of London made it impracticable for him to continue his work, so he retired to the neighbourhood of the Upper Thames, where he lived quietly until the end came.

Medical Notes in Parliament

Physical Standard of Returning Miners

On December 2 Mr. BEVIN, replying to Mr. Rhys Davies, said that the physical standard laid down for ex-miners returning to the pits for underground work was that examiners should be satisfied that a man's general physique was such as to enable him to undertake work at or near the coal face. Examiners were asked to give special attention to cases where valvular disease of the heart might be suspected. Men were to be rejected if found to be suffering from any disease of the following classes: (1) all forms of tuberculous disease; and (2) all cases of uncontrollable hernia. These instructions were issued after consultation with the medical inspection staff of the Mines Department, and after consideration of the parallel conditions laid down for other cases of special recruitment. Doctors were paid a fee of 5s. for each man examined. Members of medical boards examining men under the National Service Acts were paid at the rate of 2 guineas a session for the first five sessions in a week, and 1½ guineas for any subsequent sessions in the week. The chairman received an additional half-guinea. About twenty-five men were examined at a session, which normally lasted for two and a half hours.

Maternity Accommodation in Scotland.—On December 2 Mr. JOHNSTON informed Mrs. Hardie that in the past two years nearly 500 new maternity hospital beds in Scotland had been made available. Nearly 100 further beds would shortly be provided in buildings at present in course of erection. He was advised, however, that shortage of beds was not a significant factor in the increase in maternal mortality.

Neonatal Deaths in Scotland.—Mr. TOM JOHNSTON told Dr. Kennedy on December 4 that in Scotland stillbirths were not increasing. A slight rise in neonatal deaths has occurred in 1941. It was, he said, too early to say whether the rise was temporary or not. Everything possible was being done by the Ministry of Food and the health authorities, central and local, to ensure the nutritional needs of expectant mothers were met. Free and cheap milk schemes were in full operation. Communal feeding arrangements were vigorously pursued.

Medical Examination of Workers from Ireland.—There is no regular medical examination for workers coming to Great Britain from Eire or Northern Ireland. Such workers are in some cases medically examined in their home areas at the instance of the employers engaging them. The authorities have power to take certain action, Mr. ERNEST BROWN added on December 4, in regard to workmen coming from Ireland who may have tuberculosis or venereal disease.

Universities and Colleges

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examinations indicated:

M.D.—W. M. E. Anderson, R. S. W. Baker, M. C. Wood.

FINAL MEDICAL EXAMINATION.—M.B.: L. H. Shrago, J. R. Hassard, J. Dorothy H. Webster, Ethna M. MacCarthy, L. H. Citron, C. E. Williams, Florella Starritt, J. A. Pearce, J. B. Dunlop, Kathleen M. J. Morphy, J. N. Greene, Muriel Eakins, B. Marcus, A. R. B. Jackson, E. S. Odbert, M. B. Flanagan, R. O. D. Reid, T. L. Kelly, A. C. McReynolds, Margaret F. Y. Dixon, Catherine E. Craig. B.Ch.: Emmeline P. Crowe, N. J. Anderson, L. H. Shrago, Dorothy W. M. Last, J. P. Walsh, A. J. B. MacFarland, A. C. McReynolds, L. H. Citron, J. Morris, J. A. Pearce. B.A.O.: J. F. Dignan, *Brenda R. Boydell, J. M. Ali, J. K. J. Swanepoel, J. A. M. Jacobson, J. Cecilia J. Dippenaar, J. S. B. Stein, J. Rena Becker, Franziska G. Brill, J. W. Dignan, D. M. Brooks, V. O. Stewart, Lavinia F. Nightingale, B. Novis, R. C. Rylance, P. J. Mentz, J. W. van der M. Roos, I. E. P. Cope.

DIPLOMA IN PUBLIC HEALTH.—Part II: Leila Finegan.

* With first-class honours. † With second-class honours.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—J. G. Atherton, J. K. Brown, J. H. Hilditch, S. H. Jackson, Heskel Khazam, N. A. Lewtas, N. S. Marsden, Ann L. Pinson, G. J. Shanklin, H. G. B. Slack. Part I: J. A. L. Cooper, Hyme Lempert, S. W. Stanbury.

THIRD M.B., CH.B.—Pathology and Bacteriology: O. E. Adeniji-Jones, J. S. Battersby, D. C. A. Bevis, D. H. Blakey, H. M. Blaquiere, D. L. Boardman, D. L. Clarkson, O. O. Cowpe, Frances G. Danson, H. Davies, C. J. Dewhurst, P. B. Duncan, B. I. Einhorn, Margaret Garnett, J. Grayson, E. J. Guest, G. Hargreaves, J. Hinchcliffe, C. L. Holden, J. C. Howarth, F. Jackson, G. W. H. James, F. W. Johnson, F. Kratter, Marjorie T. Lee, Mary P. McGlade, R. I. Mackay, D. H. Makinson, A. Marsland, E. B. N. Merchant, Doreen Mitchell, J. G. Oddy, Shelem Portnoy, P. T. Quinlan, S. B. Rampling, F. C. Reidy, A. F. Robinson, R. H. Sewell, J. H. Shelswell, Sylvia M. Slee, K. H. Smith, H. Sosnowick, J. L. Taylor, R. Pepper, Lois E. N. Turner, E. G. Wade, Ruth J. Whitley, T. A. Yates. Pharmacology: H. W. Ashworth, W. C. Astley, F. Batley, D. G. Berry, R. W. Burslem, J. H. Diggle, *Constance M. Duddle, Doreen M. M. Dutton, B. I. Einhorn, S. S. Epstein, Eve G. Field, K. Heilbronn, J. Heppelstone, J. Hewet, R. Hierons, Marion E. Jepson, P. Jewsbury, F. Latham, Margaret M. Lawton, J. Leary, *L. A. Liversedge, Marion B. T. McIntosh, H. McIntyre, H. B. Marsden, T. M. Martin, Joan A. Mettam, B. Nicholson, T. A. Nowell, *S. Oleesky, A. D. Robinson, L. Rose, P. W. E. Sheldon, L. Shuck, H. Tabbush, A. E. Thomas, Elizabeth Travers, G. S. Tupman, P. Vulfsons, W. V. Wadsworth, G. H. Watson, B. Wilkins, P. O. Yates.

* Distinction in pharmacology.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH
At the annual meeting of the Royal College of Physicians of Edinburgh, held on December 4, Dr. Charles McNeil was re-elected President and Dr. R. B. Campbell, Dr. L. H. F. Thatcher, Dr. D. M. Lyon, Dr. A. G. Ritchie, Dr. L. S. P. Davidson, and Dr. A. Rae Gilchrist were elected to form the Council of the College for the ensuing year. Dr. Lyon was nominated vice-president.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 29.

Figures of Principal Notifiable Diseases for the week and those for the corresponding London.

are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941					1940 (Corresponding Week)

EPIDEMIOLOGICAL NOTES

Discussion of Table

Measles was the only infectious disease in England and Wales which showed a big rise in the number of notifications. 211 cases, when compared with the preceding week. This rise in incidence was due to relatively large increases in a few administrative areas. Outbreaks in the boroughs of Battersea and Wandsworth were responsible for the increase of 26 cases reported in London. Outbreaks occurred in Kent, Malling R.D.; Hereford, Leominster M.B.; and Shropshire, Bridgnorth M.B., where the notifications were 23, 39, and 23 respectively in excess of those of the previous week. The figure for cerebrospinal fever, which exceeded the total of the preceding week by 26, was the largest for the past four months. The other infectious diseases tended to be slightly below the level of the preceding week. The largest decreases were shown by whooping-cough and diphtheria, with 36 and 35 fewer cases. The only local variation of any size was shown by whooping-cough in Surrey, where in Carshalton U.D. notifications rose from 7 to 20, and in Sutton and Cheam M.B. from 9 to 20.

In Scotland small increases were recorded for the third consecutive week in the number of notifications of cerebrospinal fever and scarlet fever. There were 6 fewer cases of measles and 25 fewer of whooping-cough than in the previous week.

Dysentery

The notifications of dysentery were 12 below the total for the preceding week in both England and Wales and Scotland. A further 23 cases were reported from the outbreak in Shropshire, Ellesmere U.D. The largest of the local outbreaks reported during the week in England were: Oxfordshire, Oxford C.B., 11; Northumberland, Gosforth U.D., 12; Cumberland, Border R.D., 21. In Scotland the largest returns were those of Edinburgh (14) and Renfrew County (10).

Pneumonia

Until the past four weeks the trend of the notifications of pneumonia has not displayed any very striking differences from that of preceding years. The rapid increase in notifications during the last month (the numbers have been more than doubled) has resulted in the incidence reaching a higher level than has been recorded for the similar period in recent years. The total notifications recorded in the 46th, 47th, and 48th weeks for the last three years are:

Division	1941	1940	1939
London	129	116	103
South-East	216	164	96
South-West	98	76	61
South Midland	231	160	115
Eastern	147	79	63
West Midland	492	364	198
North Midland	265	147	117
North-Western	694	449	317
York	276	238	228
Northern	237	160	144
Wales	212	116	137
	3,187	2,684	1,579

As the population has been disturbed by war conditions a comparison of areas for the pre-war periods was not attempted. The figures show that the increase in pneumonia has been common to the whole country but that the rate of increase has varied considerably. The largest relative increases are those of the South-Eastern and Eastern Counties and the smallest those of London and the South-Western Counties.

The Reich Finance Minister, together with the Minister of the Interior, has published an order regulating State payments for the third and subsequent children: These payments shall not be made in the case of "asocial" families. This applies to children with serious hereditary diseases or when the parents suffer from a hereditary disease. Payments can also be refused if the children have "foreign blood" and also for children whose parents will not belong to the various party organizations. "It is not congruous with the aim of this relief that it should be paid to heads of households who are not willing or are not fitted to serve faithfully the Reich and the people or who offer no guarantee for the suitable use of such assistance."

Medical News

In pursuance of Section 1 of the Rules Publication Act, 1893, the Minister of Labour and National Service proposes, at the expiration of forty days from December 5, 1941, to make regulations under the Factories Act, 1937, extending the provisions of Section 66 of the Act to toxic anaemia. Copies of the draft regulations may be purchased directly from H.M. Stationery Office at the following addresses: York House, Kingsway, London, W.C.2; 1206, George Street, Edinburgh; 31-41, King Street, Manchester, 1; 1, St. Andrew's Crescent, Cardiff; or through any bookseller.

The Central Association for Mental Welfare (24, Buckingham Palace Road, S.W.1), the Child Guidance Council (temporary address, 23, Queen Square, Bath), and the National Council for Mental Hygiene (Chandos House, Palmer Street, S.W.1) continue to publish as a joint undertaking the quarterly *Mental Health*. The October issue (1s. post free) includes two papers on observed effects of wartime conditions on children, and the address given at the last annual meeting of the National Council for Mental Hygiene by Mr. Kenneth Walker entitled "The Need for a Positive Philosophy of Life." The Child Guidance Council provides a note on play therapy, and there are the usual news paragraphs and reviews of books.

According to the *Yorkshire Post* of December 6, approaches are to be made by the Harrogate Wells and Baths Committee to the British Spas Federation to call a national meeting to discuss plans for making British spas available for national health insurance patients, for obtaining the co-operation of friendly societies, and for using the spas for the benefit of industrial workers.

The British Standards Institution announces that, in view of the continuing expansion of its work and the development of its relations with Government Departments and with standardizing authorities over-seas, the General Council has appointed an executive committee under a permanent chairman, Mr. C. le Maistre, C.B.E.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles should communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE No.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, Aitiology Westcent, London; SECRETARY, Medisecra Westcent, London.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Income Tax

Second Year of New Practice

E. S. was assessed for the first year of his present practice on the current year's basis. The receipts included a special non-recurring amount of £118. He is being charged for the second year on the previous year's basis, thus having in effect to suffer assessment twice on this special receipt.

* Section 15 of the Finance Act, 1930, provides that in such circumstances E. S. can, by giving notice to the inspector of taxes, require both (but not one only) of the second and third years of assessment to be dealt with on the basis of the profits of each of those years. The notice must be given in writing within two years of the end of the second year of assessment, and may be revoked within twelve months after the end of the third year of assessment.

LETTERS, NOTES, ETC.

Treatment of Scabies

Dr. W. A. DICKSON (Garryowen, Enniskillen) writes: Now when our present greatly increased fluid population of troops and evacuees has added considerably to the importance of the treatment of scabies, Dr. Berncastle's letter (October 18, p. 560) regarding the use of sulphur taken internally has revived some interesting memories. Fifteen or more years ago my late father—medical officer in charge of two adjoining dispensaries in this county—gave, as is usual, his newly qualified son some useful advice, among which was a short discourse on scabies. I might explain that part of his district was composed of bleak and mountainous areas where many of his patients were in very poor circumstances, and had not the facilities for an elaborate course of treatment, including baths, changes of apparel and bedclothes. His advice boiled down to this: in all but the mildest cases treat both internally and externally, and his treatment consisted of:

Sulph. praecip.	1 oz.
New milk	1 pint
Malt vinegar	1/2 pint
Treacle	2 drachms

Bring to the boil slowly. After boiling allow to settle and cool and decant supernatant fluid, adding thereto ess. menth. pip. 1/2 drachm, of which mixture give 2 drachms t.i.d., and if necessary increase to 1/2 oz. t.i.d. Remove about half the sulphur sediment and mix same with lard 2 oz. and liq. carb. deterg. 1 drachm. This ointment to be applied and rubbed into affected areas.

In following out his advice I had evident proof of the efficacy of this treatment in the case of a family of eight, where father, mother, and six children, the latter ranging from 16 years to an infant in arms, were heavily infected—especially the parents and eldest daughter, with many raw areas and ulcers of the nipples. No baths were available except for the two youngest, and the supply of spare underclothes and bedclothes was almost non-existent, yet in ten days all were clear except the infant. They had all taken the mixture (in varying amounts) except the infant.

Again, about ten years ago at one of the outlying county schools in my area I found about one-third of the children (fifty-eight present) suffering from scabies. I knew full well that in spite of any advice I might give many would either not consult their medical attendant or, if so, would only carry out his instructions in a most haphazard manner, and that, therefore, the condition was not likely to improve within any reasonable time. I remembered having stopped at a delightful roadside spring and almost nauseated myself with a gulp of its sparkling waters, which I found to my disgust to be heavily charged with sulphur. As this spring was less than half a mile from the school I instructed the master to get a small wooden pail of the water brought to the school each day and to see that every child drank about an ounce of it each day. I visited the school about eighteen days later and found the condition cleared. As the spring is now non-existent, due to some natural cause which I have been too lazy to try to elucidate, I had completely forgotten about this incident until Dr. Berncastle's letter recalled it to my memory.

Anti-tobacco Campaign

Dr. A. ROSE (London, W.C.1) writes: Referring to the anti-tobacco campaign in Germany and Prof. Hans. Reiter's article in particular (noted in your issue of November 22, p. 758), I think it is about time that we, the medical men of this country, also tried to combat, in a body, the evils of tobacco-smoking. We constantly see in our consulting rooms the injurious effects of this common habit, when it is carried to excess, in the jumpy and nervy individual who is amblyopic in the dark. At this time, when more cigarettes are smoked than ever before, and we see at every turn their baneful influence, it would be wise to warn the people to lessen or to annul their output of smoke if we really are to possess an A1 nation at last. An intensive campaign of organized propaganda against the consumption of tobacco is at the moment being financed by the German State, to be undertaken in the newspapers, theatres, cinemas, and all places of public assembly.

British Schering, Ltd., inform us that although sulphacetamide appeared in Class B of the supplement to the Medical Research Council's memorandum on economy in drugs, indicating that it is in short supply, they have so far been able to meet all demands for "albucid" of British manufacture.

Messrs. T. J. Smith and Nephew, Ltd., Neptune Street, Hull, have now issued a second edition of their pamphlet on the Preparation of Plaster Casts, with special reference to the use of wide "Cellona" material. Surgeons interested in this technique may have copies, free of charge, on application to the makers.

"GROWTH" AND THE DIABETOGENIC ACTION OF ANTERIOR PITUITARY PREPARATIONS

BY

F. G. YOUNG, D.Sc., Ph.D.Lond.

(From the National Institute for Medical Research, London)

Joslin (1940) states that about 80% of his adult diabetic patients are, or have been, over weight at the time they come for treatment, and excessive weight is widely recognized as a frequent characteristic of the elderly diabetic patient. White—quoted by Joslin (1940) and by Coggeshall and Root (1940)—finds that at the onset of diabetes a substantial proportion of her diabetic children are above the average height for their age, and many of these show precocious physical development. In discussing these facts Joslin (1940) asks the pertinent question, "In the child growth is vertical, in the adult it is lateral. Is not each type of endocrinal origin?" The results of the experimental investigation described in the present paper indicate, in relation to the evidence already in the literature, that a positive answer might be given to Joslin's question in terms of pancreatic-hypophyseal balance.

The first demonstration of the diabetogenic action of anterior pituitary extract in normal animals was made by Evans, Meyer, Simpson, and Reichert (1931-2) under interesting conditions. Two puppies which had been treated daily with a growth-promoting preparation of ox pituitary gland, and had thereby increased to about twice the weight of control animals, were found to be suffering from polyuria and glycosuria. Two treated litter-mates did not develop this diabetic condition. Using the intact adult dog as a test animal, Young (1939) subsequently found that ammonium sulphate fractionation of a crude extract of ox anterior hypophysis resulted in the precipitation of the diabetogenic principle in the pseudoglobulin fraction, in which it was accompanied by the growth-promoting substance (assayed on the adult intact female rat). Other investigators, using partially depancreatized rats as test objects for diabetogenic activity, have also found a similarity in properties between the growth-promoting and diabetogenic substances (Shipley and Long, 1938). When it is recalled that both Evans, for the growth hormone, and Houssey, for the diabetogenic substance, have strongly emphasized the importance of using absolutely fresh glands for the preparation of active extracts, and of carrying out all procedures at low temperatures, it becomes surprising that more cases have not been recorded of the development of a diabetic condition in the puppies in which gigantism has been produced by treatment with growth-promoting pituitary extracts.

A possible explanation lay in the observation that an adult dog effectively treated with diabetogenic extract for some days eventually developed a refractory state, such that the symptoms of diabetes disappeared during a period of continued similar dosage, though they would reappear if the daily dose of extract were suitably increased (Young, 1937, 1938). It was therefore possible that the puppies treated with growth hormone did exhibit a transient

response to the putative diabetogenic action of the extract, but subsequently became refractory to this aspect of its action, while retaining sensitivity to its growth-promoting effect. It seemed desirable to investigate this point, using extracts with a diabetogenic action demonstrable in normal adult dogs.

Growth hormone preparations induce retention of nitrogen (Evans, 1941); and Mirsky (1939) has obtained evidence that this nitrogen-retaining action may be mediated, in part at least, by the islets of Langerhans of the pancreas. An investigation was therefore undertaken of the relation between the nitrogen-retaining and pancreotropic actions of anterior pituitary extracts, in permanently diabetic animals in which some islet tissue remained. By pancreotropic activity is meant that action of pituitary extracts which induces a rise in islet tissue and insulin contents of the rat pancreas (Marks and Young, 1940) and thus makes more insulin available for secretion.

Methods

Animals.—Normal adult dogs, normal puppies, and adult dogs which had been rendered permanently diabetic by a short period of treatment with anterior pituitary extract (Young, 1937) were used in the present investigation. They were housed in metabolism cages, and daily collections of urine were made under toluene. The amount of food eaten each day was determined by weighing, and was so adjusted that the adult dogs retained about 75 calories/kg./day. The puppies were given a mixed diet *ad lib.*, consisting of raw horse meat, cooked liver, dog biscuits, and milk, with vitamin concentrates twice weekly. The adult dogs received a diet of raw horse meat and liver. All the animals were weighed daily.

Anterior Pituitary Extracts.—A crude extract of fresh ox pituitary tissue was prepared, from glands brought to the laboratory in a frozen condition, by the method before described (Young, 1938), to which further procedures have now been added. In brief, the method consisted in extraction with saline at pH 8.5 in the cold room, followed by spinning on an international centrifuge, clarification in a Sharples supercentrifuge, and Seitz-filtration in the cold room. Bacteriological tests were carried out to ensure that sterility had been obtained. This preparation, which will be referred to as "crude pituitary extract," is highly diabetogenic in normal dogs and cats, and contains most, if not all, of the active principles in the anterior lobe of the ox hypophysis. An unfractionated pituitary extract, which had no detectable diabetogenic action when tested on the intact normal dog but otherwise resembled crude pituitary extract in general activity, was obtained by allowing the sterile crude extract of fresh ox pituitary gland to remain at room temperature for four months. This preparation will be described as extract ND.1. An extract of acetone-desiccated ox anterior lobe powder, which had been stored in the laboratory in a dry condition for some months, was prepared in a manner essentially similar to that for the extract of fresh tissue. This preparation, which was also non-diabetogenic in normal dogs, but resembled crude pituitary

extract in exhibiting manifold activities, will be referred to as extract ND.2. These three unfractionated extracts were of such concentration that 1 c.cm. contained in each case the material extracted from 250 mg. of fresh anterior lobe tissue or its equivalent—i.e., approximately 50 mg. of dried tissue.

A preparation of prolactin, which was obtained by the Bates-Riddle method and which was highly pancreotropic, was used in one experiment. This was the same preparation as that used previously in investigations on pancreotropic activity in rats (Marks and Young, 1940).

All injections were made subcutaneously with aseptic precautions.

Estimations.—Urinary sugar was determined by Benedict's method and urinary ketones by the method of van Slyke. Nitrogen estimations on food, urine, and faeces were arrived at by the Kjeldahl method. Although frequent analyses for the nitrogen content of food were made, these, and faecal nitrogen determinations, were not carried out daily, so that the figures for nitrogen balance are not quantitatively precise, although on the whole the results were agreeably constant. Blood-sugar determinations were made on capillary blood by the Hagedorn-Jensen method.

Action of Crude Pituitary Extract

(a) **Normal Adult Dogs.**—In eight experiments on four dogs (2 male, 2 female) averaging 10 kg. in weight, 5 c.cm. of extract injected subcutaneously each day never failed to produce a substantial glycosuria within seven days. The mean time of the appearance of glycosuria was 5 days (maximum 7, minimum 4) and the average sugar excretion was 23 gm. (maximum 44, minimum 11) on the first day and 58 gm. (maximum 74, minimum 39) on the second day of the diabetic state. The amount of extract required by the subcutaneous route is thus very much less than that necessary when the injections are given intraperitoneally (Young, 1938; Houssay, Foglia, and Smyth,

extract which progressively increased from 5 to 20 c.cm./day, and then fell to 5 c.cm. again, while the other two (Nos. 125 and 127) received 5 c.cm./day throughout. Three of the puppies showed no trace of urinary sugar at all, while No. 124 gave a trace on the fifth, sixth, and ninth days of treatment, the maximum twenty-four-hour yield being 1.6 gm. (0.5 gm./kg.) on the sixth day of treatment. No trace of ketone was found in the urine at any time. On the basis of these results we can assume that an average dose of 3.3 c.cm./kg. is not an effective diabetogenic agent in the puppy, this being more than six times the dose fully effective in the adult animal. After a total of 19 weeks' treatment No. 124 had reached a weight of 20 kg., compared with the weight of about 8 kg. which he would have attained if his average pre-treatment rate of growth had been continually maintained over this period. At this time he presented the characteristic features of experimental gigantism in dogs, as described in the classical experiments of H. M. Evans—large paws and head, thick and heavy bones, excessive growth of skin, etc. Up to this time he had been sugar-free despite the continuation of daily injections, but later a gradually increasing glycosuria became apparent. At present, after 23 weeks of treatment, his glycosuria has risen to nearly 200 gm. daily and he has stopped growing, his weight having remained around 20.5 kg. for the last three weeks. Nos. 125 and 126, which have received daily injections for 23 and 19 weeks respectively, have not responded to the prolonged growth-promoting action of the extract so strikingly as dog 124, nor have they yet developed a diabetic condition.

Action of Non-diabetogenic Extracts on Pituitary-diabetic Dogs

If the nitrogen-retaining action of pituitary extracts is mediated by the pancreas, as Mirsky (1939) has suggested, then non-diabetogenic pituitary extracts which are pancreotropic (Marks and Young, 1940) might be expected to cause nitrogen retention, increase in weight, and an alleviation of the diabetic condition of at least a temporary duration in animals which are diabetic but have some secretory islet tissue remaining.

In the experiments carried out in this connexion, a single injection of extract was administered to diabetic dogs after a suitable control period. As might be expected, it was found that the response to any given extract was apparently determined by the intensity of the diabetic condition of the treated animal. Thus treatment with a preparation of prolactin which in the rat test is highly pancreotropic (Marks and Young, 1940) permanently increased the D/N quotient of moderately diabetic dog 115 (Fig. 2, A), inducing a sharp rise in ketonuria, which,

FIG. 1.—The influence of daily subcutaneous injections of crude anterior pituitary extract on the body weights of puppies. The figures below the arrows indicate the daily dose of extract, in c.cm., given from that day onwards. The dotted lines represent the best straight line fitted to the data for the pre-treatment control period.

1941). We have found our adult dogs remarkably constant in their response to this extract, and it seems reasonable to assume that 0.5 c.cm./kg. (equivalent to 25 mg. dry weight of anterior lobe tissue per kilogramme of body weight), administered subcutaneously each day for at least a week, is more than enough to induce a temporary diabetic condition in adult dogs.

(b) **Normal Puppies.**—Each day four puppies (2 male, 2 female) were given subcutaneous injections of crude extract that were very much larger per kg. of body weight than those required to produce diabetes in adult dogs (Fig. 1). Two of the puppies (Nos. 124 and 126, Fig. 1) received daily doses of

FIG. 2.—Influence of a single subcutaneous injection of various anterior pituitary extracts on the course of diabetes in pituitary-diabetic dogs. The injection was given on the days indicated by the arrows. The initial and final points on each curve represent average values for approximately one week. The intermediate points represent daily values.

Experiment A, Dog 115: Injection of 160 mg. of prolactin
 B, " 118: " " 5 c.cm. of extract ND.1
 C, " 122: " " 5 c.cm. of extract ND.2
 D, " 118: " " 5 c.cm. of extract ND.2
 E, " 122: " " " " "
 F, " 118: " " " " "
 G, " 118: " " " " "
 at a time when the dog was receiving 5 units of protamine-zinc-insulin daily
 H, " 122: Injection of 5 c.cm. of extract ND.2 when the dog was receiving 15 units of P-Z.I. daily
 I, " 118: Injection of 5 c.cm. of extract ND.2

however, was only temporary. It must be emphasized that this preparation was non-diabetogenic when tested in large doses in the intact adult dog (Young, 1938), and the same is true of all the extracts considered in the present section. The sustained rise in D/N quotient occasioned by a single injection of this extract suggests that permanent damage had occurred to that pancreatic islet tissue which was still capable of secreting insulin.

Extract ND.1, also pancreotropic in the rat, raised the D/N quotient of mildly diabetic dog 118 (Fig. 2, B) from an initial control value of 1.5 to a final approximately constant figure of 2.3 with a substantial loss of nitrogen and of body weight (B in Table). Again permanent islet damage seems to be indicated.

Table showing the Influence of a Single Injection of Anterior Pituitary Extract on the Condition of Diabetic Dog 118

Exp. (Fig. 2)	Length of Period (Days)	Treatment (Single Injection of Extract)	Food Intake (Calcs. Daily)	Sugar Excreted (Gm./Day)	Corrected D. N	Nitrogen Balance (Gm./Day)	Change in Body Weight (Gm./Day)
B	4 7	Control 5 c.cm. ND.1	1,520 1,420	63 121	1.58 3.10	-0.5 -4.2	0 -100
D	7 8	Control 5 c.cm. ND.2	1,140 1,380	52 15	1.54 0.33	-3.5 -5.0	-35 -50
F	7 7	Control 5 c.cm. ND.2	1,850 1,910	107 127	2.32 2.45	-1.9 -3.1	-30 -60
G	7 7	Control (5 U. of P.-Z.-I. daily) 5 c.cm. ND.2 (5 U. of P.-Z.-I. daily)	1,200 1,200	33 14	0.78 0.39	— -4.2	0 -100
I	10 1 1	Control 5 c.cm. ND.2 —	900 900 620	81 99 87	3.60 3.64 3.19	-2.7 -2.9 -13.6	-55 0 -650

(The data given are the average daily values for the various periods.)

When dog 122, whose D/N quotient was at a level of 3.4, was given a single dose of the same extract the only obvious effect was a sharp but unsustained rise in ketonuria. It is interesting to recall that when pituitary-diabetic dogs which are exhibiting a maximal D/N quotient associated with a substantial ketonuria are given a small daily dose of insulin, the D/N quotient may be largely unaffected while the ketonuria may be strikingly reduced (Marks and Young, 1939). The response of dog 122 to a single injection of the pituitary extract (Fig. 2, C)—a response which is similar to that obtained with many other dogs under comparable conditions—seems to be the converse of that with insulin described earlier, and to indicate that the main effect of the extract has been temporarily to neutralize the action of what little insulin the damaged islets are still capable of secreting.

When dog 118 was in a mildly diabetic state he responded to a single injection of extract ND.2 by a temporary but striking fall in the D/N quotient (Fig. 2, D), with a retention of nitrogen and an increase in body weight (D in Table); but later, when his diabetic condition had become more severe, with a control D/N quotient of 2.3, he resembled dog 122 (Fig. 2, E) and failed to show any very obvious response to an injection of the same extract (Fig. 2, F; F in Table). When, however, the diabetic condition of dog 118 was partially controlled by insulin therapy he again showed a temporary fall in D/N quotient in response to a single injection of the same extract (Fig. 2, G), with nitrogen retention and rise in body weight (G in Table), although the opposite result occurred when dog 122 received an injection of the same extract at a time when his diabetic condition had been reduced to about the same degree of intensity by insulin therapy (Fig. 2, H). Finally, when dog 118 had become severely diabetic, with a control D/N quotient of 3.6 and a daily ketonuria of about 0.3 gm. of total acetone, a single injection of extract ND.2, which previously had temporarily alleviated his diabetic condition, now killed him in diabetic coma (Fig. 2, I), with a rapid loss of nitrogen and of body weight (I in Table) and a terminal blood-sugar level of 0.56%.

From the data for the various experiments on dog 118, given in the Table, it is clear that when treatment with extract alleviated the diabetic condition it also induced nitrogen

retention and an increase in body weight (D and G in Table), but that if the conditions were such that a single injection of extract exacerbated the diabetes it also induced loss of nitrogen and of body weight (B and I in Table).

Discussion

The present observations indicate that if the extracts used by H. M. Evans in his classical experiments concerning the influence of growth-promoting pituitary preparation on puppies had been fully diabetogenic when tested on adult dogs a condition of diabetes would not be expected to develop in treated puppies until after many months' daily injections, if at all. Thus it is possible to produce experimental gigantism without diabetes, even though the pituitary extracts used are diabetogenic in adult dogs or cats.

The results of this and previous investigations show that the same pituitary extract may be essentially growth (weight)-promoting, or essentially diabetogenic, according to the age of the animal and the adequacy of its pancreatic function. In the intact adult animal (dog or cat) both responses may be manifest simultaneously, although the diabetogenic effect ultimately becomes predominant; while in the young puppy the only obvious response to treatment with the same extract is that of accelerated growth. The fact that with normal cats and normal dogs an increase in body weight is associated with the induction of a diabetic condition by the administration of crude pituitary extract has already been emphasized (Young, 1937, 1938). Now, Ogilvie (1937) has presented quantitative evidence that human infants have a greater amount of pancreatic islet tissue in proportion to body weight than adults. If such a difference holds for the puppy and the adult dog, then the resistance of the puppy to the diabetogenic action of pituitary extracts which are highly effective in the adult dog receives a simple explanation. Furthermore, Langfeldt (1920) found that partially depancreatized puppies, which had been deprived of a sufficient proportion of pancreas to provide a reasonable expectation of the appearance of diabetes in an adult dog, not only were free from all symptoms of diabetes for many months after the operation but in some instances showed an increase of sugar tolerance. Eventually, however, the sugar tolerance declined and a progressive and ultimately fatal diabetes became manifest. The present results concerning the diabetogenic action of anterior pituitary extracts in puppies are in many ways analogous to those of Langfeldt.

The results of our experiments on the influence of pituitary extracts on diabetic adult dogs (Fig. 1 and Table) are consistent with Mirsky's idea that the nitrogen-retaining action of the extract is mediated by the islets of Langerhans, but it should be pointed out that Gaebler and Galbraith (1941), as the result of investigations with completely depancreatized dogs, do not believe that pancreatic insulin is the only factor concerned. Indeed, Gaebler and Robinson (1941) have recently found that on depancreatized bitches receiving a constant dosage of insulin prolactin exerted only a mild diabetogenic action but induced some storage of nitrogen. Clearly some action other than a pancreotropic one was exerted by the pituitary preparation in this instance. The present results are not incompatible with such an action, but under the conditions of our experiments it seems reasonable to assume that the main nitrogen-retaining action of the extracts used was mediated by the pancreatic islets. If this is so, the differences in response to the same extract with differences in intensity of the diabetic condition can be reasonably explained in terms of two antagonistic effects—pancreotropic and diabetes-intensifying (diabetogenic ?)—of the extract, the first tending to induce secretion of insulin with nitrogen retention and an increase in body weight, while the second

intensifies, or tends to intensify; the diabetic condition, presumably by suppression of carbohydrate oxidation, etc. (Russell, 1938), or perhaps by increased sugar formation from fatty acids (Soskin, 1941). If the pancreatic islets are capable of responding to the pancreotropic action of the extract to a sufficient extent when the diabetes is uncontrolled (exp. D, Fig. 2 and Table), or after it has been partially controlled by insulin with consequent rehabilitation of islet tissue and insulin storage (exp. G), then the diabetes-intensifying action of the extract may be completely overcome (however, cf. exp. H), so that treatment with the extract causes temporary alleviation of the diabetic condition, with an increase in body weight and storage of nitrogen. But if the islets cannot respond to the pancreotropic action of the extract to such an extent the extract may have no obvious effect (exp. F, Fig. 2 and Table), or may cause an intensification of the diabetic condition which may be only temporary (exp. C and H) or may lead to death in coma (exp. I). With an extract possessing enough diabetes-intensifying activity, a suitable animal may show a persistent exacerbation of the diabetic condition (exp. A and B, Fig. 2) which is presumably associated with permanent damage to the tissue of the pancreatic islets. Gaebler (Gaebler and Zimmerman, 1939-40) found that pituitary extracts which caused growth and nitrogen retention in normal animals showed a marked diabetogenic action in depancreatized thyroidectomized bitches receiving adequate insulin therapy. Phloridzinized animals reacted, on the other hand, by a rise of body weight and nitrogen retention, with diminished glucose excretion and a constant D/N quotient (Gaebler and Zimmerman, 1939-40). In connexion with the action of our extracts in causing temporary alleviation of the symptoms of pituitary-diabetic animals, with a fall in D/N quotient, it is interesting to note that Haist, Campbell, and Best (1940) find that when such dogs are given a series of injections of crude pituitary extract during a period of fasting, together with very large injections of insulin at frequent intervals, the sugar tolerance of the animals may subsequently show substantial improvement.

It is undesirable to enter here into a discussion of the identities of the active principles concerned, but it should be pointed out that the results indicate that the pancreotropic factor in anterior pituitary extracts is not identical with the diabetes-intensifying factor.* Thus in experiments B and D (Fig. 2 and Table), in both of which dog 118 was initially at the same level of intensity of diabetes, a single injection of one extract induced temporary though marked alleviation of the diabetic condition (exp. D), whereas a different extract raised the D/N quotient and apparently caused permanent damage to islet tissue (exp. B). It therefore seems that the two factors—pancreotropic and diabetes-intensifying—are present in different proportions in these two extracts, and thus cannot be identical. Nevertheless, differential inactivation of different active groupings carried by the same (protein ?) vector cannot be left out of consideration, and the same possibility applies to the previously demonstrated non-identity of the pancreotropic and diabetogenic (intact dog) factors (Marks and Young, 1940). But as we have no evidence on this point it will not be further considered.

Although extracts which are devoid of diabetogenic activity when administered in large doses to the intact dog are capable of intensifying the diabetes of diabetic animals (cf. also Long, 1937), we do not know whether extracts

with diabetogenic activity differ quantitatively or qualitatively from those with only diabetes-intensifying action in the diabetic animal, but it should be emphasized that diabetes-intensifying activity can be completely masked if an extract possesses enough pancreotropic activity and the treated animal has enough responsive islet tissue (exp. D, Fig. 2 and Table).

The presence in the human infant of a large proportion of islet-tissue (Ogilvie, 1937) is probably associated with the importance of insulin for nitrogen retention, etc., during the period of growth. If an infant were submitted to a long period of low-grade pituitary overaction the pancreatic islets might at first respond with hypertrophy, so that the child would possess capacity for a greater degree of nitrogen retention and growth. The islets might be incapable of sustaining indefinitely such an intensified activity, and once the general blood-sugar level rose irreparable derangement of islet function might result in persistent diabetes. In the adult person the hypertrophic phase of islet response would, analogously, result in an increase in body weight, and it is of particular interest that Ogilvie (1933, 1935) found that a large proportion of the obese subjects he examined revealed hypertrophy of the pancreatic islets. If such a condition is a pre-diabetic one an extra-pancreatic cause of the diabetes seems extremely probable. Is it therefore unreasonable to suppose that the increase in weight of the pre-diabetic human adult may have an origin similar to that seen in the normal adult dog (and cat) treated with anterior pituitary extract—namely, a slight, and possibly ill-sustained, increase in anterior pituitary action? Such a slight increase in pituitary activity as would be necessary to induce a rise of body weight would not necessarily be associated with obvious symptoms of gigantism or acromegaly; nor would it be expected, at least in the majority of cases, to endow the plasma of the patients with anti-insulin activity, demonstrable in tests on rabbits. Even in diabetes associated with frank acromegaly, insulin sensitivity is comparable to that found in normal diabetes (Coggeshall and Root, 1940). Although this question lies outside the scope of the present investigation, it may be suggested that where obvious adiposity of the human pre-diabetic adult exists it may well arise, to some extent at least, from changes in dietary habits (cf. Himsworth and Marshall, 1935; Richter and Schmidt, 1941), possibly resulting from the inhibition of glucose oxidation by pituitary principles (Russell, 1938).

Conclusion

If the above arguments be accepted the pre-diabetic increase of height in children and of weight in the adult can be regarded as a reactive or protective mechanism for the storage of the carbohydrate of which the oxidation is suppressed, and of the nitrogen which is retained, under the influence of anterior pituitary action. The expansive capacity of the adult is definitely limited, and unless the child is capable of sustained excessive growth (the limit to which may be the capacity of the islets to hypertrophy) there will come a point, as was probably the case with dog 124, at which the carbohydrate the oxidation of which is inhibited can no longer be completely stored in the form of extra body tissue. Sugar then leaks into the blood stream, and despite a subsequent and complete subsidence of pituitary overactivity, permanent stigmata may remain in the form of islet lesions and a persistently diabetic condition. It is interesting to note that the rat, which is capable of substantial and sustained response to the growth-promoting action of pituitary extract even in ripe old age, is almost completely resistant to the diabetogenic action of crude pituitary extract (Young, 1938), although sensitivity can be induced by partial pancreatectomy (Long,

* The word "diabetauxetic" (Greek *αἰξίνω*, to increase), analogous with "diabetogenic," might be useful to describe factors which are capable of intensifying the diabetic condition where diabetes already exists but which are not obviously diabetogenic in suitable intact animals. Similarly, "diabetostatic" might be used to describe factors capable of alleviating the intensity of a diabetic condition by inducing the pancreas to secrete more insulin.

1937, 1939). The above interpretation of experimental findings cannot in any sense be considered as attempting to exclude the possibility that clinical diabetes may result, in some instances, from primary changes in the pancreatic islets—e.g., those which follow interference with the pancreatic blood supply, and in haemochromatosis (cf. Warren, 1938). Nevertheless, the large number of cases of diabetes in which a definite increase in the mass of the body is apparently a proleptic feature may reasonably be supposed to result from a pancreatic-pituitary imbalance occurring at a level of pancreatic islet activity higher than that operative in the normal animal.

Summary

When puppies are treated daily with doses of crude pituitary extract greatly in excess of those required to produce diabetes in adult dogs they respond with an increased growth rate but do not exhibit symptoms of diabetes. When one puppy was treated daily for nearly five months it eventually became intensely diabetic, and then stopped growing despite continuation of treatment.

When adult dogs that have been rendered permanently diabetic by a short period of pituitary treatment are given a single injection of pancreatropic pituitary extracts, which produces no detectable diabetogenic activity in normal adult dogs, the response may be a transitory attenuation of the diabetic condition with nitrogen retention and increase of body weight, or an exacerbation of the diabetes with loss of nitrogen and of body weight; intermediate responses were also obtained. These differences in response are believed to result largely from differences in functional capacity of pancreatic islet tissue.

It is suggested that an increase in body weight, associated with an increase in function of the pancreatic islets, can be regarded as neutralizing, for a time at least, the diabetogenic influence of the anterior pituitary gland. It is therefore possible that the excessive weight of the adult diabetic patient and the abnormal height of the diabetic child (White) indicate an increased pituitary function which may be of temporary duration only, and of which the diabetogenic action may be completely masked for a time by a protective increase in pancreatic islet activity, induced by the pancreatropic action of the gland. Such a condition might lead first to an increase in the mass of the body and eventually to diabetes.

The preparation of the extract used in this investigation was largely carried out by my assistant E. A. Woollett, and the sterilizing filtration by F. A. Holbrook. For the skill and perseverance of these two technical assistants I wish to express my thanks and gratitude.

TREATMENT OF PULMONARY TUBERCULOSIS BY THORACOPLASTY

BY

F. RONALD EDWARDS, M.D., Ch.M., F.R.C.S.

Assistant Thoracic Surgeon, Lancashire County Council;
 Assistant to the Professor of Surgery, University of Liverpool

G. LEGGAT, M.B., Ch.B., D.P.H.

Medical Superintendent, High Carley Sanatorium, Ulverston

AND

H. MORRISTON DAVIES, M.D., MChir., F.R.C.S.

Thoracic Surgeon, Lancashire County Council

Pulmonary tuberculosis is a disease whose incidence rapidly increases during wartime, and it is important in the present situation that the treatment of this condition should remain in the forefront of discussion. From the public health point of view no patient who is suffering from pulmonary tuberculosis should return to work until his sputum is negative. In our crowded factories and offices any such person with a sputum positive for tubercle bacilli is an anachronism, and subversive both to the health of the community and to the war effort. Under the present conditions of long hours of work, continued stress, and minimal nutrition the dissemination of the disease from one such focus may be considerable.

Thoracoplasty is applicable as a line of treatment to only a small percentage of cases of pulmonary tuberculosis. The results are, however, satisfactory in that in most cases the patient, previously a public menace, becomes non-infective and is able to return to some form of useful occupation.

The following is an account of the indications for thoracoplasty in the treatment of pulmonary tuberculosis as used by the team working at the surgical clinic of the Lancashire County Council Tuberculosis Service at High Carley Sanatorium, Ulverston.

Indications for advising Thoracoplasty

This is probably one of the most difficult problems in the whole of surgery. Only by the closest team-work between the surgeons, the staff of the sanatorium, and the anaesthetist can these cases be accurately assessed. The cases are divided into two groups—those regarded as “good risks” and those as “justifiable risks.” The latter group will contain a number of patients suffering from advanced disease in which the risks of thoracoplasty are greatly above the average. These risks are, however, permissible because there is a definite possibility that by running them the disease may be arrested, and because by no other method of treatment can the patient's life be saved. Apart from the consideration of the individual patient, there is another cogent reason why the immediate and ultimate chances of the patient must be most fully weighed. Sanatorium life is such an intimate one that every patient is fully aware of the results of operative treatment on others, and in order that those in the “good” class shall have no misgivings as to the outcome of their operation the fullest confidence in the results of thoracoplasty must be maintained.

There are certain general principles which influence the selection of cases:

1. The tuberculous lesion must be undergoing fibrinosis and must not be in a state of acute exudation. Rapid compression of the lung, such as occurs by thoracoplasty, is likely, in cases with an acute exudative lesion, to cause a rapid dissemination of the disease with infiltration of the same or opposite side. If, however, the disease is in a reparative stage—i.e., under-

going fibrosis—the lung will stand this rapid compression without such risk of further spread of the tuberculous lesion. A lung lesion which is healing by fibrosis without coexisting cavity formation can become bacillus-free, can heal, and can probably remain healed without the need for operative intervention, though the end-result may be benefited by hemidiaphragmatic paralysis. It is the persistence of chronic cavitation that constitutes the danger to the patient and to the community. A chronic fibrotic case without clinical or radiological evidence of cavitation which does not become bacillus-free should be tomographed, when the presence of cavities will almost certainly be demonstrable. The large majority of cases coming up for consideration for thoracoplasty are those in which a cavity or cavities have failed to close as a result of sanatorium treatment and in which an artificial pneumothorax has proved impossible or ineffectual. Most of these cases have very definite symptoms: the sputum is abundant and loaded with tubercle bacilli, and they may be persistently pyrexial. The general health of others, as a result of prolonged sanatorium treatment, may be good; in some, even, the cavity may be dry, the sputum (if any) tubercle-free, and the symptoms minimal. It may seem drastic to recommend a major operation such as thoracoplasty to patients who are apparently well enough to return to their homes and even to work. The long view must be taken, however, from both the individual and the public health aspects. Sooner or later the disease will light up again, as a result either of overwork or of coryza or influenza. Not only may the disease spread to those parts of the lung or lungs previously involved, but, more serious still, the patient will become an infecting agent for a shorter or longer time before again being taken under control.

Repeated haemoptyses, whether or not associated with obvious cavitation, provide an additional indication for thoracoplasty, as does also a chronic non-productive irritable cough following upon distortion of the trachea and bronchi due to massive pulmonary fibrosis consequent on partially healed tuberculosis.

2. The main tuberculous lesion must be unilateral. After a total thoracoplasty the patient has only the lung on the opposite side left with which to breathe. If there is an active tuberculous lesion, however small, in this remaining lung, there is considerable likelihood that this lesion will increase and will eventually prove fatal. An old lesion on the contralateral side which is radiologically and clinically healed should still be viewed with suspicion, as any extra work of that lung may cause it to reactivate. It must be remembered that the tubercle bacilli, although surrounded by dense fibrous tissue, are in most cases merely dormant and not dead. Calcification may be taken as a fair indication of death of the tubercle bacilli. The final assessment of the condition of the opposite lung must be based on the clinical examination, and never solely on the radiographic appearances. The slightest evidence of activity should cause the decision for operation to be postponed, pending a further period of rest in bed. Crepitations which are persistently present and unaltered at the opposite apex are not a contraindication. These cases with contralateral evidence of disease or instability are included in the "justifiable risk" group. It is in the assessment of such doubtful cases that the opinion of the medical superintendent of the sanatorium is of great value to the team. A pronounced opinion by him, as a result of his continuous observation of any individual patient, will often tip the scale when decision is in the balance.

3. The size and position of the cavities will influence the decision as to whether thoracoplasty will be of permanent benefit. It may be asserted as a general rule that the smaller the cavity and the less extensive the lesion the easier it is to obtain complete control by a thoracoplasty. Complete control of cavities near the hilum or in the base is more difficult than control of those in the upper lobe. Large cavities, especially if surrounded by a thick wall of fibrous tissue, are not readily compressed. Extensiveness of the disease, provided it is unilateral, is no contraindication.

4. As pneumothorax is the simplest form of collapse therapy it should have been tried in all cases. If the pneumothorax is impossible, or is producing inefficient collapse of the affected area which cannot be improved satisfactorily by internal pneumolysis, then thoracoplasty must be considered. Any residual

pneumothorax should be allowed to reabsorb or be removed before thoracoplasty is attempted, as collapse of the ribs is prevented when there is a cushion of air between these and the lung.

5. Although no absolute age limits can be given it is generally inadvisable to perform a thoracoplasty for pulmonary tuberculosis under 15 years or over 45 years of age. In children it is inadvisable owing to the exudative form of disease that occurs and also the subsequent effect on growth. In the more elderly the cardiovascular changes and the diminished ability of the remaining lung to compensate for the loss of aerating surface may be contraindications. Exceptions to this rule are, however, not uncommon.

6. The better the general condition of the patient the greater is the probability of success. Once it is accepted in a given case that healing of the lesion cannot be obtained except by a thoracoplasty, then, however well stabilized the patient may be for the time being, it is wrong to wait for the period of decline to set in. When, on the other hand, the general condition is poor the operation must be deferred in the hope that improvement can be effected by bed rest, even at the risk of a relapse or extension of the disease during this period of delay. Amyloid disease if advanced will contraindicate operation, but if mild this should clear up when the pulmonary lesion heals following thoracoplasty. A transient gastro-enteritis will delay operation, but an established tuberculous enteritis is a direct contraindication. Involvement of the larynx does not necessarily prohibit operation unless there is ulceration causing pain or oedema producing stridor: healing will be promoted once the infection in the lungs has been obliterated. The presence of other lesions, such as bone and joint tuberculosis and genito-urinary tuberculosis, only contraindicates operation if these are advanced. Anaemia should be treated by haematinics. The main thing to be remembered is that tuberculosis is a general disease of which the lung lesion is but a local manifestation. The lung is, however, in most cases the important lesion, and as such should be given prior consideration. Elimination of the pulmonary focus will cause improvement elsewhere. If the patient is the subject of recurrent bronchitic attacks or has an asthmatic tendency, thoracoplasty should not be undertaken.

The Operation

The standard operation employed at this clinic is the ten-rib paravertebral thoracoplasty with removal of the transverse processes, done occasionally in two, but more often in three, stages. Partial thoracoplasties are rarely undertaken. This procedure is considered only in the type of case with extremely limited disease in one apex, and then as an alternative to an extrapleural pneumothorax. Most lungs with apical lesions show involvement to some degree, generally of the mid-zone, and often of the lower zone. Furthermore, the lymphatic interconnexions between the various parts of the lung are so numerous that the tuberculous infection extends over a much wider area than the clinical or radiological evidence would suggest. The partial collapse of a lung produces between the collapsed and uncollapsed portions of the lung a line of tissue strain in which it is no infrequent occurrence to see later a reactivation of the disease. It is admitted that in some cases a total thoracoplasty does produce an apparently unnecessary collapse of seemingly healthy lung with some resultant loss of vital capacity, but it is felt that the disease is much more securely arrested.

Anaesthesia is produced by a preliminary induction with 6 to 10 c.cm. of intravenous barbiturate, followed by inhalation of oxygen with 3 to 5% of chloroform vapour to maintain narcosis. Infiltration of the whole operative area is undertaken with 1% kerocain (procaine), and at the stage of rib exposure the intercostal nerves are infiltrated as they pass out on to the neck of the ribs. It is our opinion that, while the operation is performed essentially under local anaesthesia, light narcosis should be maintained throughout.

The first stage of the operation consists in the removal of the whole of the first and second ribs up to the costal cartilages and 13 cm. of the posterior ends of the third and fourth ribs. The third and fourth transverse processes are also removed. At the second stage, undertaken fourteen days later, 13 cm. of the fifth to eighth ribs inclusive are removed together with the transverse processes. At the final stage, a fortnight after, 13 cm. of the ninth and tenth ribs are removed. Occasionally the operation is performed in two stages by removing five ribs at each stage. The wound is drained for twenty-four hours through a separate stab incision.

Considerable pressure is maintained laterally and anteriorly on the collapsed portion of the chest after the first twenty-four hours by means of elastic strapping and pads of wool and sorbo rubber. Weights are applied later on to the front of the chest to assist the collapse, and finally an elastic brace is fitted which maintains constant pressure on the chest for some months. Exercises are given to counteract the tendency to scoliosis and to regain full arm movements. Rest in bed is continued for two to three months after the operation.

Results

During the period 1933-40 59 cases of pulmonary tuberculosis were treated by thoracoplasty; 52 were for parenchymatous disease and 7 for tuberculous empyema. 158 operations in all have been performed on these patients. The follow-up results, undertaken in May, 1941, are as follows:

TABLE I.—Cases of Parenchymatous Disease

	Fit and Well, with Negative Sputum	Unfit or with Positive Sputum	Now Dead	Total
1933 ..	1 (100%)	—	—	1
1935 ..	3 (100%)	—	—	3
1936 ..	5 (62.5%)	1	2	8
1937 ..	4 (67%)	1	1	6
1938 ..	3 (67%)	1	1	5
1939 ..	4 (57%)	2	1	7
1940 ..	10 (67%)	4	1	15
Total ..	35 (68%)	9 (17%)	8 (15%)	52

35 patients (68%) are now fit and well, and 30 (88%) of these are able to do their daily work. Nine are still unfit or have a positive sputum (see Table V). Eight patients have died since the operation was undertaken. No death due to post-operative shock occurred, but four of these patients died within three months of the operation. Details of the cases can be seen by reference to Table V (Cases 8, 11, 14, 15, 20, 21, 34, 48).

Of the 52 patients 40 were considered "good risk" cases for thoracoplasty and 12 "justifiable risks" (see Fig.). The results in these two groups were as follows:

TABLE II

	Good Risk	Justifiable Risk
Fit and well, with negative sputum ..	30 (75%)	5 (41.7%)
Unfit or with positive sputum ..	5 (12.5%)	4 (33.3%)
Now dead ..	5 (12.5%)	3 (25%)
Total ..	40	12

There is a tendency to increase the number of "justifiable risks" operated upon, and in some of the later cases the disease would have been deemed extensive enough to contraindicate operation in the early days. A further analysis of the "justifiable risk" group of cases reveals the following figures:

TABLE III.

	Fit	Unfit*	Dead	Total
1935 ..	1	—	—	1
1936 ..	—	1	1	2
1938 ..	—	2	1	3
1939 ..	—	1	1	2
1940 ..	4	1	—	5

It is as yet too early to forecast the outcome in the 1940 group of "justifiable risk" cases, but one feels a certain degree of apprehension regarding their future. It is possible that by performing total thoracoplasty in this group too much strain is put on the remaining lung, and that a more localized thoracoplasty with maintenance of function of the lower part of the lung may produce better results. It is still important, however, in assessing the line of treatment in this group, to bear in mind the objections to localized thoracoplasty which have been mentioned before.

It is interesting to study the group of cases with large cavities—i.e., 5 cm. or more as measured on the A.-P. radiograph.

TABLE IV

Size of Cavity	Fit	Unfit	Dead
5 cm. ..	4	3	—
6 cm. ..	—	—	—
7 cm. ..	2	1	—
8 cm. ..	—	1	—
9 cm. ..	—	—	1

The value of thoracoplasty in producing collapse of giant cavities has been disputed, and it would appear from this small group of cases that patients with cavities of certainly 6 cm., or over, would be better treated by preliminary suction drainage to reduce the size.

The only satisfactory criterion by which to assess the results of thoracoplasty is a comparison with a similar group of cases in which thoracoplasty has not been done—i.e., those refusing operation. Unfortunately it has not been possible to obtain any figure for such cases from this centre, but they would at any rate be very few in number. Comparable figures have, however, been published by Hurford (1941) and Freedlander and Wolpaw (1937) which show that in the operated group the disease was arrested in 65% (Hurford) and 57% (Freedlander and Wolpaw), and in the unoperated group in 16% (Hurford) and 10% (Freedlander and Wolpaw).

Approximately 50% of all cases considered for possible thoracoplasty on presentation of the history and films are turned down on clinical examination owing to the presence of too active disease on the opposite side or to the general condition of the patient not being up to standard. The cardiovascular system of many of these patients is in an unstable condition due to continued toxæmia, and would be an added hazard to the operation. As more and more experience is gained in this branch of surgery there is a tendency to perform thoracoplasty on increasingly "desperate" cases, with the idea of giving the patient a chance to recover. While such a procedure is justifiable, as death is certain in so many cases in one to two years, the danger of bringing the operation into disrepute must always, as mentioned before, encourage a certain degree of conservatism.

How soon should thoracoplasty be undertaken in these cases of fibro-cavernous disease? There is probably a growing tendency to operate earlier, but any degree of exudation must delay thoracoplasty until fibrosis has occurred. Moreover, the exposure of a patient to the risks and consequences of a major operation before every

other method of treatment has been given the fullest trial is deprecated. It is possible that the advent of surgery has encouraged a tendency to haste in the treatment of a disease in which time, bed rest, and sanatorium treatment are essential principles.

One feature of this operation is the scoliosis that occurs towards the side on which the thoracoplasty has been undertaken. The degree of scoliosis is probably somewhat greater if the transverse processes have been removed than

if they have been left, owing to the temporary loss of attachment of the erector spinae group of muscles. This, however, can very effectively be overcome by encouraging the patient to lie on the operated side from the beginning. The degree of scoliosis appears more severe in the radiograph than on clinical examination. When the patient is clothed the deformity is negligible. The advantage claimed for the more efficient collapse of the lung when the transverse processes are removed in our opinion outweighs the

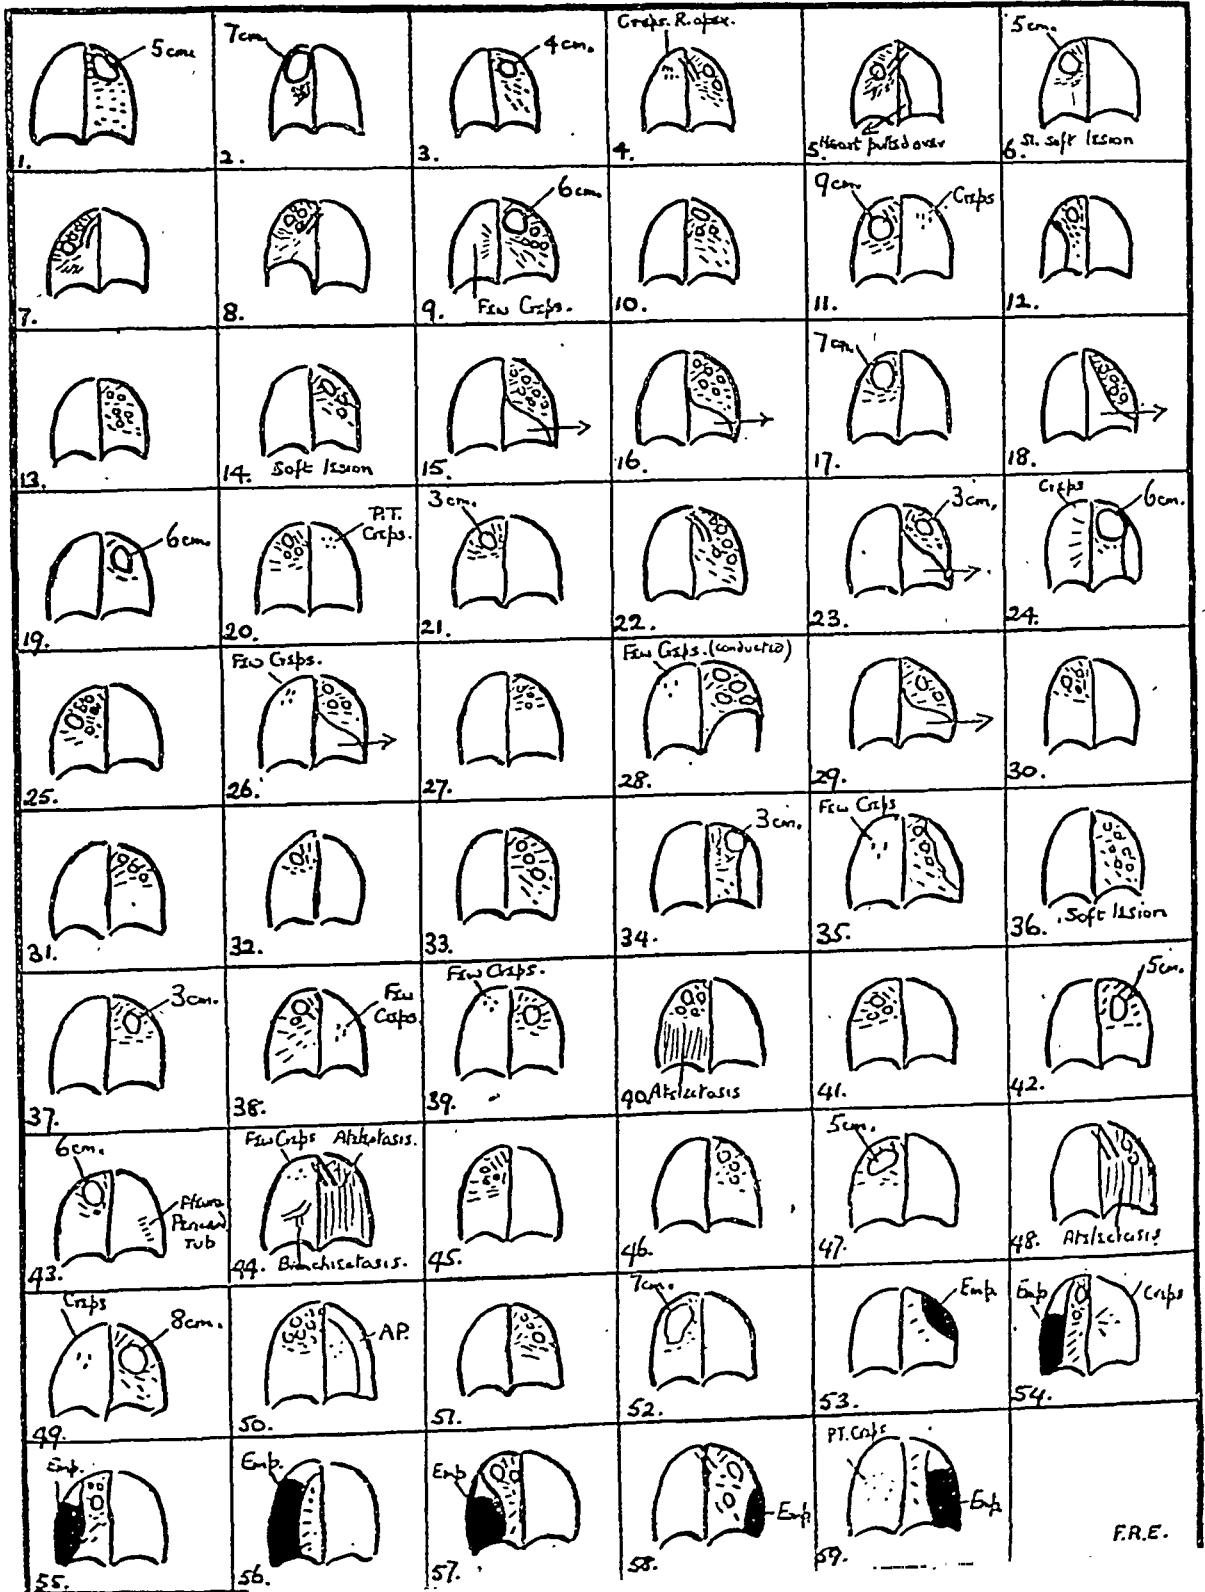

TABLE V

PRE-THORACOPLASTY										POST-THORACOPLASTY

resulting scoliosis. All too often, when the transverse processes are left, the persistence of an elongated, flattened, but not wholly obliterated cavity can be seen in the costo-vertebral sulcus.

Tuberculous Empyema.—Of the seven subjects of tuberculous empyema treated by thoracoplasty, five are dead, one is alive but deteriorating, and one is well and cured of his tuberculous empyema but still requires a small plastic operation to complete the epithelization of the remains of the cavity. All cases had been treated conservatively for a long period before being presented for thoracoplasty. Operation undertaken at an earlier date before the general effects of the continued toxæmia become too marked and the pleural membranes too thickened would undoubtedly produce more satisfactory results.

Summary

From the public health point of view no person with a sputum positive for tubercle bacilli should be at large in the community.

Thoracoplasty will arrest the disease in a certain proportion of cases and allow return to work.

Indications for thoracoplasty are: The disease should be in the fibrotic stage, and must be mainly unilateral; pneumothorax should have been tried; the cavities should not be too large. The age limit is given as 15 to 45, with exceptions. The general condition of the patient should be good.

Ten-rib paravertebral thoracoplasty with removal of the transverse processes is the operation of choice.

Results at the surgical clinic of the Lancashire County Council Tuberculosis Service in the period 1933-40, with follow-up in May, 1941, are given. Fifty-two cases were operated on for parenchymatous disease: 35 (67%) are fit and well, with negative sputum, and 30 (86%) of these are working.

Seven cases were operated on for tuberculous empyema, with total arrest of the disease in one case only. These cases should be operated on earlier.

Our thanks are due to Dr. G. Lissant Cox, Central Tuberculosis Officer, Lancashire County Council, for permission to publish this report. We acknowledge the great help given to us by the tuberculosis officers of the county in the follow-up of these cases. Our greatest appreciation is due to the members of the medical and nursing staff of High Carley Sanatorium for the after-care of these most difficult patients. The anaesthesia was conducted by Dr. John Halton.

Hurford, J. V. (1941). *Lancet*, 1, 693.

To meet urgent needs, some of them arising out of the war, four new teaching departments have been set up at Leeds General Infirmary. One is a department of thoracic surgery, another is a school of physiotherapy, the third is a school of radiography and radiotherapy, and the fourth is a school of dietetics. An account of these developments is given in the *Yorkshire Post* of November 21. The thoracic surgery department is especially noteworthy, and by its inauguration Leeds becomes the first of the teaching hospitals in the Provinces to take this step. The founding of the school of physiotherapy has been expedited by the war, for the establishment of such a school, with its own building, was until lately no more than a suggestion for post-war development. Damage to London hospitals has led to the immediate demand for a physiotherapeutic instructional centre elsewhere. The course at Leeds will occupy two and a half years, and is intended to prepare students for the examination of the Chartered Society of Massage and Medical Gymnastics. At the school of radiography and radiotherapy students are in training for the examination of the Society of Radiographers during a two-year course which, as a war measure, will be reduced to six months. The school of dietetics gives six months' practical training for those who have done the theoretical work at a college of domestic science. It will function in close contact with the special kitchen set apart by the Leeds General Infirmary for the preparation of food for patients on a special diet.

AN IMPROVED METHOD OF REGIONAL ANAESTHESIA IN ACUTE ABDOMINAL SURGERY

BY

N. R. JAMES, L.R.C.P.Ed., D.A.

Anaesthetist, E.M.S.; late Assistant to the Department of Anaesthetics, University of Oxford

AND

H. W. BURGE, M.B., B.S., F.R.C.S.

Resident Surgical Officer, Radcliffe Infirmary, Oxford

The advantages of regional anaesthesia in grave abdominal cases have long been recognized. While in America and on the Continent the work of such pioneers as Crile, Labat, Finsterer, and others has been received with enthusiasm, regional anaesthesia has never achieved popularity in this country. This, we think, is because (1) most patients dislike being conscious during an operation; (2) the administration of a regional anaesthetic is often in itself an ordeal for even the most stoical patient; (3) too often anaesthesia proves to be incomplete, and deep general narcosis is found necessary.

Types of Regional Anaesthesia

The forms of regional anaesthesia in use to-day are as follows:

Spinal Anaesthesia.—(a) Subarachnoid Block:—By this method an extreme degree of relaxation of the abdominal muscles is obtained together with what Farr describes as "negative intra-abdominal pressure." If the anaesthetic ascends as high as D 5 splanchnic block is also obtained. The liability to grave falls in blood pressure and the risks of sudden collapse make spinal anaesthesia (subarachnoid block) unsafe except in comparatively fit patients. (b) Epidural Block:—The work of Dogliotti (1933) and Odom (1936) aroused interest in this method. It is now generally considered that epidural block is neither reliable nor safe.

Field Block.—This method is the most popular in use owing to its comparative safety and ease of administration, and may well be associated with the work of Finsterer (1923). Although anaesthesia at the site of incision is usually adequate, relaxation is often poor; this is a serious defect in an exploratory operation. "Negative intra-abdominal pressure" is absent, and protrusion of the abdominal viscera often occurs, especially if the patient strains; this may be aggravated by inadequate preliminary sedation and rough handling of the viscera by the surgeon. Sometimes, after the abdomen has been opened, it becomes clear that the first incision must be extended or a fresh incision made; local infiltration or additional field block may then be necessary if deep general narcosis is to be avoided. To protect the patient from the effects of traction on the viscera, field block is often supplemented by splanchnic block, the most popular technique being that of Braun (1924).

Infiltration Anaesthesia.—This method, so strongly advocated by Farr (1930), has recently been used by Vishnevsky (1938), Synovich (1940), and Novikov (1940). Injection of large quantities of dilute anaesthetic solution—e.g., equal parts of 0.25% novocain and 1 in 4,000 pericaine—into the fascial pockets surrounding muscles and viscera generally requires the use of a power-driven pump; the aspiration test cannot be performed, and there is always risk of mechanical breakdown. Infiltration anaesthesia carries with it all the disadvantages of field block.

Bilateral Paravertebral Block.—If a true paravertebral block is performed in the manner originally suggested by Sellheim (1905) and perfected by Labat (1922) then the rami

communicantes and the sympathetic nerves are blocked as well as the intercostal nerves. If this procedure is repeated bilaterally from D 7 to D 12 then excellent abdominal anaesthesia and relaxation occur; a substitute for splanchnic block is, in addition, obtained. Unfortunately this otherwise excellent method has grave disadvantages. Skill above the average is required to place the point of the needle at the exit of the vertebral foramen. The difficulty of accurate injection makes this method unreliable. Ever present is the well-known danger of injecting anesthetic solution into the prolongations of the subarachnoid space along the spinal-nerve roots. The all-important aspiration test may then be wrongly interpreted owing to cerebrospinal fluid being colourless. Paravertebral block is not a practical proposition in the hands of the average anaesthetist and surgeon.

Bilateral Mid-axillary Intercostal Block.—Here the intercostal nerves are injected in the mid-axillary line, generally from D 7 to D 11. This method has always enjoyed a certain amount of popularity, and quite recently has been recommended by Bartlett (1940). It has the disadvantage that having injected the intercostal nerves on one side the anaesthetist must change position, prepare the skin, and repeat the injections on the other. If the anaesthetist wishes to perform splanchnic block by the posterior approach of Kappis, which for reasons stated later we prefer to the anterior approach of Braun, the patient must undergo a change of posture, with fresh skin preparation and rearrangement of towels.

An Improved Method of Regional Anaesthesia

We believe that the method here recorded is free from the major disadvantages of the techniques described above. It has six main features: (1) adequate pre-operative omnopon (pantopon) sedation; (2) the preliminary use of a short-acting barbiturate—e.g., hexobarbitone B.P. (evipan); (3) posterior bilateral thoracic-nerve block; (4) bilateral splanchnic block by the posterior approach; (5) oxygen therapy with the B.L.B. mask; and (6) attention to gentleness in operative technique. A detailed description of the method follows.

Preliminary Sedation

If no sedative has been given before admission, or if sedation has been inadequate, then as soon as consent for operation has been obtained the patient receives an intravenous injection of omnopon. We use the drug intravenously because of its rapid action by this route and because, by giving it slowly, the dose can be regulated to the patient's requirements. The respiratory rate should not be depressed below 14 to the minute. A small dose of atropine (1/100 grain) is given subcutaneously half an hour before operation.

Surgical Preparation

In the ward a radiant-heat cradle is used, the foot of the bed is raised, and when required, as in cases of intestinal obstruction, the stomach is emptied by a small-calibre tube (Ryle or Miller Abbott), which is left in position both during and after operation. Intravenous infusion is employed when necessary: in cases of profuse vomiting, intravenous glucose saline is given; plasma or blood is used as indicated. A B.L.B. mask is applied when anoxia is suspected and in cases of intestinal obstruction with distension (Fine, Hermanson, and Frehling, 1938). When the condition of the patient has improved the abdomen and back are prepared in the usual way.

Preliminary Intravenous Narcosis

If the patient's condition permits, intravenous hexobarbitone B.P. (evipan) is given in the anaesthetic room.

Should further omnopon sedation appear necessary we find that drawing up 1/3 grain of omnopon into the evipan solution is a safe and useful procedure provided the resulting straw-coloured solution is introduced with extra slowness and caution. One of us (N. R. J.) has used this method since 1937. We prefer evipan to pentothal because after a "single" dose it gives a long light narcosis without undue depression of the respiratory and cardiovascular centres. Evipan does not diminish the oxygen capacity of the blood (Pask, 1941). Intravenous evipan with omnopon sedation not only renders the patient unconscious during the insertion of the regional anaesthetic but, if a suitable dose has been given, keeps him asleep throughout even a long abdominal operation if no unaesthetized area is stimulated. The benefits of light general narcosis supplementing regional anaesthesia and thus preventing psychic trauma were first emphasized by Crile and Lower (1920), and were recently referred to by Hewer (1940). The short-acting intravenous barbiturates—e.g., evipan—are particularly useful in that they protect against the toxic effects of regional anaesthetic solutions (Rovenstine and Cullen, 1939). Moreover, they are portable, easy to administer, and non-inflammable—virtues which are especially important in war surgery. Should the patient's condition be so grave as to make him apathetic to his surroundings, then supplementary intravenous narcosis is used only if he becomes restless during operation. It is omitted in cases of severe vomiting, for then the risk of inhaling vomitus is present even though continuous gastric aspiration is employed. The importance of maintaining a clear airway cannot be emphasized too strongly. We use a nasopharyngeal tube, made by cutting an old Magill's endotracheal tube of suitable diameter to a length equal to the distance between the lobe of the patient's ear and the alae nasae. A safety-pin is inserted through the non-bevelled end to prevent the tube being inhaled. If this short tube is placed correctly it is tolerated even in very light narcosis.

Regional Anaesthesia

Preparation of Solution.—Wearing sterile gloves, the anaesthetist prepares a 1% solution of novocain with adrenaline. We take two 1-gramme sterile ampoules of planocaine and dissolve the contents in 200 c.cm. of sterile normal saline to which is added, from a sterile ampoule, 0.5 c.cm. of 1 in 1,000 adrenaline. The sterile 10-c.cm. syringe (we use the Lundy type) and needles, which have been previously sterilized by boiling and allowed to cool gradually, are washed through with cold sterile water.

Technique of Posterior Bilateral Thoracic-nerve Block.—The patient is turned on to his left side and the vertebral column is flexed by an assistant as in spinal anaesthesia, care being taken that the airway is maintained. A small pillow is, when necessary, placed under the loin to prevent sagging of the lumbar spine. The skin is painted with 1 in 1,000 flavine in spirit and the highest points in the iliac crests are palpated to determine the intercostal line. Immediately below this line lies the fourth lumbar space, and from here the first lumbar space and then the tip of the first lumbar spine are identified. A point is taken 6 to 8 cm. (3 or 4 fingerbreadths) lateral to this spine, and here a 10-cm. needle is inserted to rest on the twelfth rib at its lower border. The syringe is now attached, and the point of the needle is made to slip off the lower border of the rib and is advanced for a distance of not more than 1 cm. The needle point now lies in the region of the neurovascular bundle, but it is difficult to know when it is just in the right fascial plane. It is therefore important that, as the injection is given, a to-and-fro movement of the needle is made; only in this way can one be sure of "hitting off" the nerve. A total of 8 c.cm. of the anaesthetic solution

is injected, and this subcostal injection is repeated up to and including D 6. The whole process is then repeated on the other side. In thin patients the ribs can be palpated, but in obese or muscular subjects they must be found by exploration with the needle. This is not difficult, but it should be noted that the tenth and eleventh intercostal spaces are appreciably wider than the preceding ones. Anaesthesia by this method is easy to perform and is associated with good relaxation of the abdominal muscles and with "negative intra-abdominal pressure." This last factor is very important in acute abdominal surgery.

Technique of Splanchnic Block.—We use a 0.5% solution of novocain with adrenaline; this we obtain by adding an equal quantity of saline to the 1% solution remaining from the thoracic-nerve block. At the site of injection of the twelfth dorsal nerve a 12-cm. needle is introduced at an angle of 45 degrees to the median plane and is advanced until its point strikes the body of the first lumbar vertebra. The needle is then partly withdrawn and advanced again more tangentially, and the procedure is repeated until the needle is felt to slide past the body of the vertebra for a distance of not more than 1 cm. If no flow of blood occurs 1 c.cm. of 0.5% anaesthetic solution is injected to clear the needle. The aspiration test is performed carefully and, if negative, the remaining 9 c.cm. is injected; the aspiration test is repeated at least once during this injection. A total of 30 to 40 c.cm. is given in this way, and the technique is repeated on the other side. It is important that the needle point should lie in the loose retroperitoneal areolar tissue and not within the substance of the crus of the diaphragm. Some indication of its true position is given by the feel of the piston as the injection is made; if the needle is placed correctly the piston is pressed home without resistance. We prefer to use this posterior approach of Kappis (1914) because: (1) the block is inserted and has time to take effect before the operation has begun; (2) the intra-abdominal manipulations of the anterior approach are avoided; (3) the anterior approach cannot be performed efficiently except through an upper abdominal incision; and (4) we have found it an efficient and safe method. Hewer states that "experimental injections made in the post-mortem room with methylene blue showed that this technique does soak the splanchnic area efficiently." He also states that "posterior splanchnic block is a reasonably safe procedure if carried out with all precautions."

Management of the Patient on the Table.—The patient is lifted on to the operating table and a pillow is placed under the knees. This small degree of hip-joint flexion improves relaxation of the abdominal wall. The legs are held in position by a padded strap passed over the thighs just above the knees. The patient's head rests on one pillow, and the hands are placed under the head in the "sun-bathing" position. The arms in this position may easily be controlled and a further intravenous injection may readily be given, if required.

Oxygen Therapy

We believe that in all grave cases oxygen therapy is of great utility. We have used it as a routine, and have come to regard it of value in every case not only during operation but also pre- and post-operatively. Waters, Wineland, and SeEVERS (1931) have pointed out that morphine and the barbiturates are two of the many factors which may cause anoxia in the surgical patient. We use a B.L.B. mask with all ports closed, the oxygen flow being adjusted to 6 to 8 litres a minute. A flowmeter should always be employed, as the flow of oxygen may be inadequate though the bag may appear to be filling properly. A reducing valve should be used if available.

Points in Operative Technique

(a) The towel clips should not include the skin. (b) An adequate incision is important: a little extra length often allows the operation to be carried out with ease and without undue traction on the viscera. (c) A vaselined glove makes insertion of the hand and exploration of the abdomen a much less traumatic procedure. (d) The adoption of the Trendelenburg position in the lower abdomen and of the reversed Trendelenburg in the upper abdomen allows the intestines to fall away and often obviates the use of intraperitoneal packs. (e) A gentle operative technique is essential throughout. Retractors and packing should be avoided where possible, and traction on all tissues should be gentle and gradual.

Scope and Indications

We are aware that we are describing no new technique of regional anaesthesia, but we believe we have evolved a method by which its long-recognized advantages in acute abdominal surgery can be put to practical use. Regional anaesthesia is often supplemented by "light" inhalation narcosis, but in many of such cases we have observed that the inhalation narcosis has been anything but light and the regional anaesthesia in reality superfluous. While the method we describe is useful in "interval" surgery, we believe it to be of most value in the "poor risk" acute abdomen. We consider that, where possible, the patient should not undergo the ordeal of being conscious during the administration of a regional anaesthetic or during the subsequent operation. The advent of the short-acting barbiturates has in our opinion revolutionized the possibilities of regional anaesthesia. We have found that after adequate preliminary omnopon a single intravenous injection of evipan (usually 0.5 to 1 gramme in the "poor risk" abdomen) keeps the patient asleep throughout even a long abdominal operation if no unanaesthetized area is stimulated. In experienced hands the method we describe is safe and reliable and is not difficult to perform. It does require practice, and the anaesthetist must be fully conversant with the use and dangers of intravenous narcosis. The application of this method to abdominal war surgery should be of value.

Summary

The various types of regional anaesthesia in present use are discussed. A new method is described. It combines: (1) adequate pre-operative omnopon sedation; (2) the preliminary use of hexobarbitone B.P. (evipan) in preference to pentothal; (3) posterior bilateral thoracic-nerve block from D 6 to D 12 inclusive; (4) bilateral splanchnic block by the posterior approach of Kappis; and (5) pre-operative, operative, and post-operative oxygen therapy, using the B.L.B. mask.

The importance of gentle operative technique is stressed.

TRICHINIASIS IN BIRMINGHAM

BY

LIONEL J. BACON, M.B., B.Ch., D.P.H.

Assistant Medical Officer of Health, City of Birmingham

An outbreak of trichiniasis occurred in Birmingham during the months of February, March, and April, 1941. Seventy-eight definite cases were reported. The first was notified to the Public Health Department with a doubtful diagnosis of trichiniasis on February 24. By this time it was known that the disease was abroad. Accounts had been published of cases in Wolverhampton (Sheldon, 1941; Lee, 1941) and in Hertfordshire (Garrod and Maclean, 1941). A warning against eating undercooked pork or sausage had been broadcast by wireless, and similar warnings had appeared in the Birmingham press.

The course of the epidemic is illustrated in the graph: it may be observed that isolated cases occurred before and

Dates of onset of symptoms of 75 cases of trichiniasis occurring in Birmingham administrative area. Vertical divisions are weeks and days. One small square = 1 case. Two additional cases had onsets on January 10 and June 15 respectively. In one other case the date of onset was uncertain. Doubtful cases omitted.

after the main outbreak. Female patients predominated (81%). Six children were affected, the youngest a girl aged 4.

Clinical Findings

In general the clinical features corresponded closely with those described by Sheldon and by Lee.

Oedema.—The most constant feature (occurring in all cases but one) was oedema of the eyelids: this was to be expected, since it was made the main criterion of preliminary diagnosis. It was of a constant and characteristic type. It was nearly always symmetrical; in only one definite case in this series and in one doubtful case was it unilateral. The whole eye-socket filled up, and in the severest cases vision was totally occluded for a few hours. It tended to spread down to the angles of the jaws. The patients were often totally unrecognizable, and appeared bloated, coarse, and much older than their years. The oedema was in most cases the initial symptom, preceding by only a few hours the other characteristic features of the "toxic" stage of the disease—fever, malaise, and generalized pains. It persisted for about a week in the moderately severe cases, and occasionally for considerably longer. Its subsidence was gradual as a rule, and there was a tendency to recurrence, especially at night-time. Oedema elsewhere than in the face and eyelids may well have occurred unnoticed in many cases, for in those in which it was observed it was slight and was mainly at the wrists and ankles. Nevertheless the most remarkable feature of the oedema is its localization.

Frontal or orbital headache was common at the onset, and was occasionally the most distressing symptom. *Conjunctival injection*, slight or severe, was the rule; in three instances there were subconjunctival haemorrhages, which in one case took the form of rings round the corneo-scleral junctions. I saw no subungual haemorrhages, though I sought them regularly. *Fever*, as evidenced by temperature records, delirium, sweating, or flushes, was observed in 30 cases. It probably occurred in many more. Where repeated observations were made it was high and remitting (e.g., 100° to 104°) for the first few days, usually returning

almost to normal during the second week. The tendency was, of course, for these observations to be made upon the severer cases. *Malaise*—i.e., a general sense of ill-being—was constant in the first few days in all but the mildest cases. It was present even in the absence of other evidence of pyrexia. *Muscular pains* or stiffness occurred in 60 patients, either with the oedema or, more often, a few hours afterwards. The site was variable. A characteristic onset was of pain between the shoulder-blades, spreading up the back of the neck to the occipital region. Later the limbs were usually affected, and in the severer cases pain and stiffness were generalized. The pain was severe, aching or cramping in quality; it was worse on movement, especially after rest. There was often stiffness, weakness, or numbness of the limbs.

Gastro-intestinal symptoms—anorexia, nausea, vomiting, abdominal pain, constipation, or diarrhoea—occurred in 39 patients. In 9 these symptoms clearly and definitely preceded the "toxic" stage, and were pronounced: and it may justifiably be surmised that they represented that point in the disease when the worms are establishing themselves in the mucous membrane of the bowel. It is interesting to note that of these 9 patients no fewer than 6 (67%) gave a history of having consumed raw sausage, whereas of the remaining 69 cases only 7 (10%) admitted to this. I attribute this significant difference to the larger dosage of viable larvae in the raw sausage. A *rash* was present in 8 only of the definite cases. In 7 of these it was urticarial in type, and coincided with the oedema. This type of rash might perhaps have been expected more often in view of the other points of similarity (oedema and eosinophilia) to allergic conditions. Indeed, urticarial rashes were the commonest cause of difficulty in diagnosis (see below). Evidences of affection of the *nervous system* were few in this outbreak. A varying degree of drowsiness, lethargy, or listlessness was frequently present, and in three patients this amounted to stupor. One patient developed a transient quadriplegia. Two patients complained of pronounced dimness of vision for a few hours at the height of the illness.

The severity of the disease was difficult to assess, since I saw most of the patients on a single occasion only, and at various stages of their illness. Many of the patients were acutely ill, but I think it is true to say that in no case did the condition give rise to grave anxiety—the pulse and respirations remained good throughout. There were no deaths.

Diagnosis

The main criteria of diagnosis were oedema of the eyelids and eosinophilia. For practical purposes it was found necessary to decide upon an arbitrary scheme of diagnosis, and the following standards were adopted:

1. Diagnosis definite—trichiniasis:			
(a) Eosinophilia 10% or more	70
(b) " 5-9%: definite clinical picture	6
(c) No eosinophil count; definite clinical picture	2
2. Diagnosis doubtful:			
(a) Eosinophilia 5-9%: doubtful clinical picture	3
(b) " less than 5%: suggestive clinical picture	3
(c) Investigation incomplete; suggestive clinical picture	2
3. Not trichiniasis:			
Eosinophilia less than 5% (or not measured); unconvincing clinical picture	16
Total	102

The eosinophilia is discussed more fully below. A "definite clinical picture" required oedema of the eyelids of pronounced degree and characteristic type without other apparent cause, or a lesser degree of oedema together with

muscular pains. It is realized that there are possibilities of error in this scheme, since other causes of oedema and of eosinophilia exist, and a mild or atypical trichiniasis may not present these features.

Group 3 were all cases notified as ? trichiniasis. They included urticarial and other rashes (9), frequently with some degree of oedema of the face or lids; "influenza" or "rheumatism"—i.e., muscular pains with or without fever or catarrh (2); mild degrees of facial oedema without other characteristic symptoms (2); paratyphoid fever (1); slight malaise without any characteristic symptoms (1); and undiagnosed pyrexia with facial oedema (1).

Biopsy was performed on two patients. In one case trichinella larvae were present in the excised muscle; in the other no larvae were found, but the muscle (gastrocnemius) showed degeneration of the fibres and infiltration by eosinophil cells. The latter patient had a 65% eosinophilia on the fortieth day of disease.

Many of the earlier cases were diagnosed only in retrospect—i.e., after it had become known that trichiniasis was about. They had for the most part been labelled "influenza," "gastric influenza," "kidney trouble," or "rheumatism." There is reason to suppose that many cases never came to the notice of the Health Department at all, either through failure in diagnosis or because they were too mild for treatment to be sought.

Blood Cell Changes

The presence and degree of *eosinophilia*, as stated above, was taken as one of the main criteria in diagnosis. Differential white cell counts were made on all but two of the cases and at various stages of the disease; it was not practicable to perform total counts, except in a few cases treated in hospital. The degree of eosinophilia showed little correlation with the day of disease. For instance, two cases of comparable severity had 5% and 44% respectively on the thirty-first day of illness. The greatest degrees of eosinophilia recorded in this series were 61% on the fourteenth day and 65% on the fortieth. The average was 24%. The reaction developed very early: a patient taken ill with swelling of the eyes and face and abdominal pain had 16% of eosinophils on the day of onset; there had been no previous symptoms. On the other hand, one patient still showed a 10% eosinophilia on the seventy-fifth day after the onset of illness, and another 4% on the 132nd day.

So far as can be judged in the absence of total counts a *lymphocytosis* occurred as well as eosinophilia. This is deduced from the fact that the ratio of neutrophil leucocytes to lymphocytes (large and small together) was markedly and consistently low (average 1.4 as against a normal of about 2.3), and that this ratio tended to fall still lower after the eighth week, when the eosinophilia was disappearing. Had the altered ratio been due to a replacement of neutrophils by eosinophils a return to normal would have been expected as the eosinophilia decreased.

The Intradermal Test

After the subsidence of the outbreak I was able, through the courtesy of Dr. Beeson of the Ministry of Health, to obtain a small quantity of trichinella antigen (a saline extract of desiccated larvae) wherewith to perform the Bachman intradermal test for trichiniasis. This test is stated to become positive about sixteen or seventeen days after infection (van Someren, 1939; Spink and Augustine, 1935), and to remain so for an indefinite period. The reliability of the test has been variously assessed. Calus (1938) found it to be positive in 74% of 66 patients (and in 5% of controls), and Heathman (1936), investigating 57

patients, regarded it as less reliable than the eosinophil count. I was informed, however, that the antigen supplied to me had been found very reliable in recent outbreaks in England, and I hoped it would prove of value in testing the validity of my arbitrary standards of diagnosis. Unfortunately the results were inconsistent in some preliminary tests on known (Group 1a) cases. Of 7 of these, 3 were positive, 2 negative, and 2 doubtful. I tested one patient whom I had classified as Group 3 ("not trichiniasis"); he had vomited on two occasions, but had had no other symptoms, and was investigated only because his wife was a doubtful case of trichiniasis. He gave a positive result; his wife was negative.

The results of these few tests are set out in the accompanying table. The numbers are too small for any conclusions to be drawn, except that the test is not by itself a reliable criterion of diagnosis. The reading of the test was complicated by the large proportion (50%) of patients

Table showing Results of Bachman Intradermal Test on Eleven Patients

Group	Result of Test			Total
	Positive	Negative	Doubtful	
1a	3	2	2	7
2a	—	—	1	1
2b	—	2	—	2
3	1	—	—	1

who gave some degree of reaction to the saline solution used as a control. The practical value of the test, except in hospital patients, is also limited by the necessity to remain with the patient for at least half an hour before a positive result can be excluded.

Inquiries into Causation

The habit of eating raw sausage reported by Sheldon (1941) and Jolly (1941) as common among people in the Midlands was found to be followed in Birmingham, where 22% of patients admitted to the habit in the past or present. Inquiries covered all forms of pork, but, though 9 patients denied having eaten sausages during a period of two weeks preceding the onset of the illness, in only one case was it felt that a probable source of infection other than sausage had been found. This was a pig's cheek. As one would expect, bacon was found to be the other commonly consumed form of pig-meat; it was not, however, eaten with anything like the frequency of sausage. In view of the inadequate curing of bacon under wartime conditions it has been suggested (Jolly, 1941) that it may convey trichiniasis. In the present investigation this was regarded as improbable in view of the fact that even lightly cooked bacon, being in thin slices, would be expected to reach temperatures lethal to trichinellae. Of the patients who had eaten sausage, only 13 admitted to having eaten it raw; while 19 were emphatic that it had been well cooked. The question of course arises, What degree of cooking is lethal to the trichinella? Also, What temperature is reached in the middle of a fried or grilled sausage? Jolly, quoting American workers, gives the answer to the former question as "55° C., gradually obtained." The latter remains, so far as I know, unanswered.

One is inclined to wonder whether the wartime sausage, with its low meat content and probably high water content, requires more cooking than the pre-war one in order to achieve this temperature throughout. Or perhaps the present-day sausage actually receives less cooking than its predecessor on account of the low fat content, which causes it to brown on the outside more rapidly, or on account of a tendency for inferior casings to burst more easily. These are matters of surmise: what is definite is that many

patients who developed trichiniasis denied with emphasis that they could in any circumstances have eaten raw sausage. A possibly significant point in this connexion is the frequency, almost amounting to regularity, with which the affected person had *cooked* the sausage, whereas usually other members of the family who had also partaken remained unaffected.

Incubation Period

Inquiries as to the number of days elapsing between the consumption of pork and the onset of symptoms yielded little reliable information owing to the difficulty of determining the day of consumption. Among 22 patients in whose case fairly definite information was obtained the average interval was seven days, but the scatter was very wide. One observation which may throw some light on the incubation period is that a group of six cases, isolated in space and time, all started their symptoms on a Saturday. Since chance is a most unlikely explanation of this, I take it to imply that in this group there was a tendency to eat sausages on one particular day of the week, and that there was a fixed incubation period. Three of these patients could give no definite date as to when they had had sausages; the other three had had them regularly on Saturdays. This suggests a seven-day or fourteen-day incubation period for this group, and the evidence pointed rather towards seven days.

Administrative Action

A circular letter was sent to all practitioners and hospitals in Birmingham drawing their attention to the prevalence of the condition, reminding them of the leading symptoms, and requesting them to notify all cases to the medical officer of health. There was some doubt as to whether the condition was compulsorily notifiable. All notified cases were visited by a sanitary inspector and subsequently (except for a few in whose case full information as to clinical picture and blood count was already available) by me. A special form, which included particulars of all pork consumed in the preceding two weeks, was completed. The retailer was visited and inquiries made as to the manufacturer or market. Acting on information thus obtained the chief veterinary officer endeavoured to trace the meat back to the farm or collecting centre. It was soon found that a large number of manufacturers of sausage were involved, including some of the biggest in the city. To trace the sources of the pork used by these manufacturers was far from easy: at that time the farmers were reducing their stock drastically owing to the rationing of feeding-stuffs, and the pigs were gathered together in collecting centres throughout the countryside, and thence distributed, not locally but over wide areas. So that the meat in a sausage eaten by one of our patients might have been derived from any one or more of several districts as far apart as Cornwall and Norfolk. Nor could observations made over a period of time be correlated, since the tendency was for each farm to kill off its whole stock and not to enter the market again.

The result of this inquiry was that fourteen widely separated districts were listed, each of which was connected (often indefinitely) with two, or in one case three, patients. It was felt that the information was not definite enough to justify further investigation at the collecting centres; and no connexion could be established between these districts and those supplying pork to other areas where trichiniasis had appeared.

Consideration was given to the feasibility of microscopically examining specimens of muscle from all sows and boars entering the Birmingham markets, but as the work involved would have been colossal, and this type of

inspection had given negative results elsewhere, it was regarded as impracticable. So reliance was placed on warning the people of Birmingham against the dangerous practice of eating raw or imperfectly cooked sausage or pork. This was done by means of notices in the daily press. It is thought that this action, while exerting little effect in terminating the outbreak, was probably influential in reducing the number of persons affected.

Discussion

It cannot be claimed that either the factors producing the outbreak or those terminating it have been at all clearly elucidated. It seems extremely likely that, as suggested by Jolly, the condition has been endemic in the Midlands for a long time, going unrecognized except during an occasional epidemic. If this be so, then it must be assumed that small quantities of trichinous pork are constantly entering the market for human consumption, and also that Midlanders regularly eat raw or undercooked pork. The latter assumption is not difficult to accept: the habit of eating raw sausage is not just a wartime one. The former suggestion is at first sight a reflection on our system of meat inspection, but in practice trichinous pork cannot be detected by ordinary inspection methods, except occasionally in a very well fed animal in which there are pronounced fat deposits at the poles of the cysts, or in very gross and very old infestations when there are many calcified cysts. Regular examination by microscopy is not practised in this country—an omission justified by the rarity of the disease.

Why did the disease suddenly assume epidemic proportions? Attempts to answer this question may follow two lines. It may be supposed that there was a sudden increase in the quantity of trichinous pork thrown on to the market; or it may be argued that changes in their feeding habits made the population suddenly more susceptible to infestation from the pre-existing source. It has already been mentioned that throughout the winter months of 1940-1 farmers were killing off their breeding stock owing to shortage of feeding-stuffs. This meant that many old sows and boars were suddenly turned into sausages. Obviously the older a pig the greater the chance that it will have become trichinized; furthermore, it is said that these older animals are far more prone than younger ones to kill and eat rats—an additional source of possible infestation which, it has been suggested, may act as a reservoir for trichiniasis in this country. A further reason why swine should become trichinized during wartime is an alteration in the constitution or diminished care in the cooking of pig-swill. It might have been expected that the cooking of swill would have been carried out with more than ordinary care during recent months in view of the prevalence of foot-and-mouth disease: I am informed, however, that shortage of time and labour has resulted in an increased laxity in this respect. Reasons for believing that people are more likely to become infested with trichiniasis during wartime, irrespective of any increase in the degree of infestation of the pork, have already been adduced. They are (1) the increased consumption of sausage owing to the shortage of other forms of meat; (2) possibly an increase in the local habit of eating sausage-meat raw, associated with an increase in the number of women who go out to work, taking their lunch of sausage-spread with them; (3) alterations in the constitution of the wartime sausage (less meat and fat, more water, and poorer-quality skin) which make for inadequate cooking.

No one of the above factors would account for the appearance and localization of the epidemic: between them they may be held to do so.

Why did the outbreak end? The killing off of old pigs is clearly a self-limited process. The consumption of raw or lightly cooked pork may have been discouraged by propaganda, though I find it hard to believe that its effect would be felt for long. The former is more likely to have been the determining factor.

To sum up, I suggest that the killing off of old stock threw a few trichinosed swine on to the market. These produced overt disease in a few localities, which were determined by the pork-eating habits of the people: there were probably a number of such localities, but in only a few did the disease become prevalent enough to attract attention and thus be diagnosed. The need to slaughter these swine was determined by economic conditions, and was of limited duration.

The outbreaks draw attention to one fact of importance—trichiniasis exists among English swine. It is probably widespread, since the Harpenden cases were believed to be associated with pigs from East Anglia, the Penrith cases with local stock, and the Wolverhampton cases with West Midland stock, while those in Birmingham may have come from any one or more of a number of districts throughout England. The infestation is probably most of the time slight, as regards both the number of pigs affected and the severity of the disease.

I am indebted to Dr. H. P. Newsholme, medical officer of health for Birmingham, for permission to publish this account. It is also a pleasure to record the willingness with which medical practitioners furnished me with particulars of their patients, both in and out of hospital.

Medical Memoranda

Crush Fracture of Sesamoid Bone of Thumb

That injury to a sesamoid bone may be the cause of the severe pain and disability of a "sprained" or "staved" thumb is suggested by the case reported below. In Pye's *Surgical Handicraft* (eighth edition, 1919, p. 205) there is a picture of an x-ray film illustrating a fractured sesamoid of the thumb. The text states: "The skiagram shows the result of a sprain of the thumb sustained by a medical student during a football match, and it will be noticed that the sesamoid bone is fractured; the thumb was forcibly hyperextended, with this result. As far as we know, this is the only case of fractured sesamoid recorded."

A man aged 62 was lightly holding the steering-wheel of his car in his right hand, the thumb being uppermost and pointing forwards and to the left, when he collided with a stationary car which had no tail light. The force of impact, though not great, was transferred through the steering column and wheel to the base of the thumb. He experienced sudden severe pain at the site, followed by stiffness and some swelling. When examined half an hour later the ball of the thumb was generally tender. Active movements of the thumb were impossible, and any attempt at passive movement resulted in great pain. The thumb was held in a semi-flexed position. A radiograph revealed no fracture or dislocation, but the sesamoid bone on the ulnar side showed a crushed appearance: the area of the shadow was increased, while the density was decreased (Figs. 1 and 2). Control films of the other hand confirmed the abnormality (Figs. 3 and 4). The hand was bandaged round a ball of cotton-wool, and complete recovery resulted in a few days.

The frequency with which such injuries occur, without a Bennett fracture or other recognized bony or articular derangement, is so well known that the term "staved" thumb is a household expression. It describes a condition causing a degree of pain and incapacity quite out of proportion to the violence of the injury. Unlike the ordinary sprain of other joints the symptoms pass off completely in a very short time. Bruising may occur, but is by no means common. Slight swelling in the region of the metacarpo-phalangeal joint is present in the early stages. Tenderness over the palmar aspect

FIG. 1.—Injured thumb; back view.

FIG. 2.—Injured thumb; front view.

FIG. 3.—Normal thumb; back view.

FIG. 4.—Normal thumb; front view.

of the joint, extending proximally into the muscles of the thenar eminence, is the most constant sign.

On account of the delicate structure of the sesamoids and the difficulty of demonstrating them clearly on the x-ray film, injury to these bones is apt to be overlooked. Effusion into the tendon surrounding the sesamoid exerts pressure on the nerve endings and causes a reflex rigidity of the muscle. It is probable that such an injury exists in most cases in which the symptoms are out of proportion to the signs and appearances.

W. HURTON SCOBIE, M.B., Ch.B., M.R.C.P., D.P.H.
Tywardreath, S. Cornwall.

E. Shaffer (*Ohio med. J.*, 1941, 37, 862) states that 1,575 cases of trichiniasis were reported in the United States during the period 1842-1914, and 2,968 were reported from 1915 to 1936, making a total of 4,543 cases during ninety-four years. The mortality rate for trichiniasis has fallen from 15.4% for 1842-1914 to 4.4% for 1926-36, indicating that more mild cases are now diagnosed and reported than formerly. There is a definite seasonal fluctuation in the occurrence of the disease, with a peak in the winter, particularly after Christmas and New Year holidays. Swine fed on garbage have trichinellae five times as frequently as do grain-fed swine, and are the principal source of human trichiniasis. If municipalities persist in feeding swine with garbage, Shaffer recommends that a law should be made requiring cooking of garbage before it is given to the swine.

Reviews

SULPHONAMIDE CHEMOTHERAPY

Sulphanilamide and Related Compounds in General Practice. By Wesley W. Spink, Associate Professor of Medicine, University of Minnesota Medical School. (Pp. 256. Approximately 16s. 6d.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co., Ltd.

Orthodox lines which have been adopted in several transatlantic books on bacterial chemotherapy are followed in Wesley W. Spink's book. Introductory chapters on general principles and the properties of different compounds are followed by instructions for the treatment of different kinds of infection. Each book on this subject has an ephemeral advantage over its predecessors, and the new features in this are up-to-date descriptions of sulphanilylguanidine and sulphadiazine, as well as a chapter on local application, a subject also referred to in those dealing with dentistry and dermatology.

The greater part of the book is a sound and simple statement of well-established facts, but a much more interesting and debatable feature is the table in which the author has committed himself to a statement of the relative merits of the three principal compounds for treating fifty-seven different conditions. Sulphanilamide is given as the first choice for all haemolytic streptococcal infections, sulphapyridine for all pneumococcal infections except meningitis and septicaemia (for which sulphathiazole is recommended), and sulphathiazole for all staphylococcal infections except meningitis (for which sulphapyridine is recommended). Sulphathiazole is advised for gonorrhoea, sulphapyridine for ophthalmia neonatorum, and sulphanilamide for gonococcal arthritis; different drugs are also recommended for meningococcal infection according to whether the meninges or the blood stream is involved, regardless of the fact that commonly both are. It is only fair to say that this table contains a good many question marks, and the author is to be complimented on so enterprising an attempt, but it would be hard to support some of his decisions by any solid evidence. Two succeeding tables list diseases in which sulphonamide compounds are of doubtful and of no value respectively; anthrax should be expunged from the second of these. A large amount of dogmatic statement is also compressed into a small space in a table of toxic manifestations caused by the same three drugs, twenty-five separate conditions being listed with seven degrees of frequency. "Common" (ranking next to "frequent") is the adjective used of the occurrence of drug fever, dermatitis, hepatic damage, jaundice, and moderate anaemia during treatment with sulphanilamide, and of the first four it is said, "may be serious: discontinue drug." This lurid picture scarcely tallies with common experience. Although these items are open to criticism, the reader will be grateful to the author for expressing his views so plainly and exactly.

STERNAL PUNCTURE

Sternal Puncture: A Method of Clinical and Cytological Investigation. By A. Piney, M.D., M.R.C.P. With a foreword by Lord Horder, M.D., F.R.C.P. (Pp. 77. 12s. 6d. net.) London: Heinemann Medical Books. 1941.

Examination of the bone marrow during life has become progressively easier, as biopsy of the tibia has been followed in succession by sternal trephine and sternal puncture. It is true that needle puncture cannot tell us all that trephining and histological sections can, but its greater simplicity for patient and operator makes it the method of choice in most instances. Increased interest in the bone marrow has been reflected in a growing literature, and shortly before the war articles and monographs on this

subject were appearing at an average rate of more than one a week. Most of these were technical and addressed to readers with a working knowledge of haematology, and there is probably still a public for the type of small primer which Dr. A. Piney has just published. After a brief historical introduction the author describes the cytology of the marrow and the "myelogram" or differential count of the normal marrow smear. There follows a description of the myelogram in the various blood disorders, infections, and protozoal diseases.

The book is written with the easy charm which has made Dr. Piney's previous books deservedly popular and should serve a useful purpose in introducing the beginner to this instructive technique. The price seems to us unduly high for a book with only 77 pages and a single small colour plate. Piney follows other authors in stating that the bone marrow in idiopathic hypochromic anaemia is characterized by a predominance of immature normoblasts, most of which are large and strikingly basophilic. Bodley Scott's work suggests that this is not in fact true, the characteristic cell in all iron-deficient marrows being a small, misshapen, polychromatic normoblast with a pyknotic nucleus. The best way to learn the technique of sternal puncture is to watch someone else carrying out the operation. Piney suggests going through the angle of Louis, which is perhaps not the easiest approach, and he does not emphasize that only a small quantity of marrow, 0.1 to 0.2 c.cm., should be aspirated.

A VARIED MEDICAL CAREER

It Passed too Quickly. An Autobiography. By Air Vice-Marshal Sir David Munro, K.C.B., C.I.E., M.B., F.R.C.S.E., LL.D. (Pp. 304. 15s. net.) London: George Routledge and Sons, Ltd.

Sir David Munro has led the eventful and happy life that justifies the title of his book. After graduating M.A. at St. Andrews he went to Edinburgh to take the M.B., Ch.B., and gives a very good word-picture of student life in these two Scottish universities. He was by temperament as much a soldier as a doctor, and this led him to enter the Indian Medical Service. The first part of his service was with Indian infantry and cavalry regiments of the North-West Frontier Force, and he describes the duties which fell to the lot of a regimental medical officer in the stirring and dangerous surroundings of the frontier outposts of India—the Malakand, Khyber Pass, Waziristan, these no-man's lands between Afghanistan and India which have ever been a source of trouble. Later he was transferred to Bengal and became deputy sanitary commissioner, which involved lecturing on public health in Calcutta University, but a longing for clinical work led him to apply for, and obtain, a district civil surgeoncy. In this capacity he found ample scope. As civil surgeon in charge of the headquarters hospital of the district he had to be chief operating surgeon, physician, gynaecologist, and pathologist. He gave the systematic lectures on public health and vital statistics at Calcutta University and was professor of mental diseases and professor of ophthalmology, while for eighteen months he combined the posts of first surgeon at the European Presidency Hospital and superintendent of the European Asylum—a veritable medical Pooh-Bah. He kept himself physically fit by sports and games—tiger shooting, racing, steeplechasing, pig-sticking, and golf: in the last-named he played in the golf championship of Northern India.

The author commanded general hospitals in Mesopotamia and Palestine during the 1914-18 war, and in 1919 he left the I.M.S. to join the R.A.F., which was starting its own medical service. He began by studying the special medical problems of aviation and rose to be Air Vice-Marshal and Director of Medical Services, R.A.F. In 1930

he became secretary of the Industrial Health Research Board of the Medical Research Council. In 1938 he was made Rector of St. Andrews University. Though written in lighter vein and for the general public, his book will be found full of interest by medical men, especially those who by force of circumstances stay at home and do not know the wide horizon, the golden land of opportunity which awaits members of the profession who go out to the Empire to practise.

PHYSIOPATHOLOGY OF THE EXTRAHEPATIC BILIARY PASSAGES

Fisiopatología del Hepato-Colédoco: Colangiografía Operatoria. By Pablo L. Mirizzi. (Pp. 279. No price given.) Buenos Aires: "El Ateneo."

The reviewer has not been able to find an existing English equivalent for the compound term "hepato-colédoco," which neatly suggests the physiological reciprocity between the hepatic duct (hepático) and the common bile duct (colédoco). In this handsomely produced and lavishly illustrated monograph the author, who is professor of clinical surgery in the University of Córdoba (Argentina), has summarized his views and experiences of the technique of radiographic visualization of the extrahepatic biliary passages by the direct injection of contrast media. The first chapter deals briefly with the anatomy of the bile passages, while the second is a rather more detailed account of their physiology, with particular reference to the hepatic and common bile ducts. In Chapter III are discussed the advantages and disadvantages of operative cholangiography and the techniques of injection and radiography. The results of the author's own experiments on thirty-seven dogs are described in the following chapter. The contents of further chapters are well indicated by their titles: V, The Normal Biliary Tree; VI, Odditis (an exhaustive account of this condition); VII, Stenosing Pancreatitis; VIII, Lithiasis (of the hepatic and common bile ducts); IX, Anomalies (of the hepatic and common bile ducts). The final and tenth chapter is devoted to a consideration of errors of technique. The bibliography is conspicuous by a complete absence of references to British sources, though French, German, and North American authors are freely cited.

Notes on Books

Of Sir COMYNS BERKELEY'S services to gynaecology, and so to the welfare of our women patients, not the least is his textbook, *Gynaecology for Nurses and Gynaecological Nursing* (eighth edition, Faber and Faber, 8s. 6d.). It contains just about as much information as can be written down profitably, as an accompaniment to experience. All that a nurse need know seems to be there, including specimens of G.N.C. examination questions, which sometimes, however, seem to ask for more than a nurse need know. The price is low, the format comfortable, the style clear, with helpful paragraphing. Though no two gynaecologists would agree on every detail, Sir Comyns Berkeley has steered through the whirlpools of controversy, and has always left room for an individual gynaecological surgeon's orders to his nursing staff. The one-page chapter on "The Bearing of the Nurse" is a gem. The tabulated systems of nursing are clear and reliable. Could the index be a little fuller next time, including, for instance, "Fistula"?

The *Proceedings of the Cardiff Medical Society* for the session 1940-1 have been published by William Lewis (Printers) Limited of Cardiff. They include an article on blood transfusion by Dr. R. Drummond, regional blood transfusion officer for Wales; reports of clinical meetings and discussions; and the text of Sir Thomas Lewis's annual address to the society on April 8, 1941, entitled "Caleb Hillier Parry, M.D., F.R.S. (1755-1822): A Great Welsh Physician and Scientist." Sir Thomas described Parry as a man who in the fullness of his career was an eminent physician

of Bath, a philosophic writer in advance of his times, a progressive agriculturist, and a clinical scientist of outstanding merit. He quotes from the clinical description that was Parry's masterpiece—the first account of the disease exophthalmic goitre, written in 1786.

Preparations and Appliances

AN IMPROVED LARYNGOSCOPE

Prof. R. R. MACINTOSH, D.M., D.A., writes from the Nuffield Department of Anaesthetics, Oxford:

The laryngoscope illustrated incorporates an epiglottis retractor and an improved method of illuminating the larynx.

FIG. 1

Epiglottis Retractor.—When the blade of a laryngoscope is inserted the epiglottis is at first pushed backwards over the laryngeal entrance (Fig. 2a). Every anaesthetist has on occasion had difficulty in everting the epiglottis so as to expose the larynx. When the new blade is used the metal elevation passes over the epiglottis, which then lodges in the notch (Fig. 2b). When the blade is withdrawn slightly the epiglottis is everted (Fig. 2c) and the larynx comes into view.

Illumination.—The orthodox illumination consists of a small electric bulb attached to the blade. This bulb is difficult to sterilize, expensive (6s. 6d.), fragile, and if it breaks in the presence of ether vapour or cyclopropane might cause an explosion. In the new laryngoscope the source of light is an ordinary robust torch bulb (price 1s.) attached not to the blade but to the battery in the handle by a flexible lead. From the bulb the light is carried to the field of operation by a pencil-shaped rod of curvelite fixed to the blade. The blade is readily detached from both bulb and handle and after use is washed and boiled.

I am indebted to Mr. R. Salt, technician to this department, for his help in making the original model. The laryngoscope can be obtained from either Medical and Industrial Equipment Ltd., of 12, New Cavendish Street, London, W.1, or Vann Bros., Ltd., 63, Weymouth Street, London, W.1.

REFRACTORY ANAEMIA

Recent improvements in the treatment of blood diseases have brought into prominence a group of cases in which the anaemia does not respond to treatment by iron or liver, although no simple cause for anaemia such as haemorrhage, toxæmia, or neoplasm can be detected. One of the first things to be suspected in such a case is leukaemia of the leucopenic type. In the early stages of subacute myeloid leukaemia neither spleen nor lymph glands may be palpable, and the presence of immature cells in the blood stream may be difficult to establish with certainty. In such cases the diagnosis can be made by sternal puncture, for the bone marrow is always infiltrated. In subacute lymphatic leukaemia the sternal puncture is not always pathognomonic,¹ but if at the same time there is no enlargement of lymph glands this diagnosis can for all practical purposes be excluded. An obscure haemolytic anaemia is another possibility, but this will be revealed by persistent reticulocytosis and an increased excretion of pigments in the urine and the faeces. In severe hepatic disease there may be a megalocytic anaemia, but the evidence of liver damage is usually obvious. Myxoedema is another condition in which pernicious anaemia may be closely mimicked. When all these possibilities have been discarded there remains a residuum of cases in which the common factor is anaemia which resists all treatment except transfusion. Bomford and Rhoads² have had the unique experience of studying sixty-six cases of this type at the Rockefeller Institute, and their findings are of wide interest.

The difficulties of nomenclature are considerable, and they prefer to call these cases "refractory anaemia." They can be subdivided, according to the appearances of the bone marrow, into four groups. In the first group the marrow is cellular and relatively mature; erythropoietic cells usually predominate over leucopoietic cells; the authors include the achrestic anaemia of Israels and Wilkinson³ in this group. The second group is the classical aplastic anaemia in which the marrow is fatty and few haemopoietic cells are present. The third group is the most difficult and disputed: the marrow is cellular with a predominance of cells somewhat resembling lymphocytes; the other tissues, however, show no evidence of lymphatic infiltration, and it is believed that the cells in the bone marrow are atypical nucleated red cells. In the fourth group there are fibrosis, sclerosis, and giant-cell hyperplasia of the marrow. The distinction between these groups is not hard and fast, and successive biopsies show that the marrow may pass

from one stage to another. Moreover, the changes in the rest of the body differ little in the four groups. Extramedullary haemopoiesis is greatest in the sclerotic type, but it occurs to some degree in all types; haemosiderosis and degeneration of liver cells may also be present in all. There is evidence that exposure to a single haemotoxin—benzol—may produce all these changes except possibly sclerosis of the marrow. Myelosclerosis differs also in the normal platelet count and the strong tendency to enlargement of the liver and spleen. Many haematologists, indeed, would regard myelosclerosis as akin to Hodgkin's disease, and of a different nature from the other three groups, which can be regarded as toxic-aplastic reactions of the marrow. The position is complicated, however, inasmuch as benzol poisoning may lead to leukaemia, and refractory anaemia may sometimes be a phase in the development of the same process.

Clinically all these refractory anaemias present much the same picture of anaemia, leucopenia, and, with the exception noted, thrombocytopenia. The colour index is usually normal or above normal, and in cases of long duration a considerable megalocytosis may develop. One of the most interesting discoveries is that the breakdown of blood is often accelerated in these patients, pigmentation of the skin and haemochromatosis are frequent, and transfused blood may be destroyed more rapidly than normal. The disease occurs at all ages, and remissions are not unusual. More than a third of the Rockefeller patients were known to have been exposed to potentially toxic agents, of which benzol and its synthetic derivatives, x rays, and radio-active materials were the most frequent. Volatile insecticides and paraphenylene diamine hair-dyes are new items in this sinister catalogue. The authors regard removal from such potentially toxic substances as the most important element in treatment; in early cases it is often curative. In some cases the toxin may be endogenous, a suggestion supported by Rhoads's earlier work on the effect of indole. Idiosyncrasy must usually be present for so severe a reaction to occur. There is both experimental and clinical evidence that defective diet may be one factor responsible for it. The proof that defective liver function is another factor is even stronger. Both biochemical and anatomical signs of liver damage can be found in many of the cases. The authors' working hypothesis of the aetiology of refractory anaemia is that "the disorder is due to a conditioned susceptibility to toxic substances, usually exogenous or endogenous aromatic hydrocarbons, associated with hepatic dysfunction, a failure of biochemical mechanisms of detoxication, and the circulation of haemolytic substances, and that these haemolysins cause either an abnormal form of haemolysis and thus an abnormal reaction in the marrow, or that they destroy both circulating red cells and developing cells in the marrow, thus producing hypoplasia or other abnormal forms of marrow."

Apart from transfusion the only remedy which seemed to have an effect was baker's yeast in large doses. In very rare cases, where haemolysis is clearly excessive, splenectomy may be contemplated, though it is in no sense a cure. Prevention must remain the most important weapon. This long paper is of more than passing

¹ *Acta med. scand.*, 1941, Supp. 112.
² *Quart. J. Med.*, 1941, 10, 175, 235.
³ *Ibid.*, 1936, 5, 69.

interest when so many of our workpeople are exposed to the hazards of potentially toxic substances in war industry. Trinitrotoluene¹ produces this same combination of liver damage and aplastic anaemia in the unfortunate few who possess an idiosyncrasy for it, and those who are working on the problems of prophylaxis and early detection of such idiosyncrasy will learn much from the ideas and technical methods which Bomford and Rhoads have developed.

THE MILK (SPECIAL DESIGNATIONS) REGULATIONS, 1941

The Minister of Health, in the exercise of his powers under the Food and Drugs Act, 1938, has recently issued as a provisional Order the Milk (Special Designations) Regulations, 1941. The Order permits local authorities to grant licences to use the special designation "pasteurized" in respect of milk which has been heated at a temperature of not less than 162° F. for not less than fifteen seconds in apparatus of a type approved by the authority. The use of the process—for long known as high-temperature short-time pasteurization (H.T.S.T.)—is therefore now officially sanctioned. The widespread employment of the phosphatase test by authorities controlling licensed pasteurization plants has in the last two or three years shown that in an alarming number of cases the terms of the licences have not been observed. This, it is to be noted, applies to the holder-pasteurization system of heating at 145° F. for thirty minutes, which alone until now has been officially permitted. It is well known that this process carried out in well-constructed and properly controlled apparatus can be relied upon to ensure the freedom of milk from living pathogenic organisms, to cause minimal damage to the nutritive and physical properties of milk, and to improve the keeping quality. This process, based on careful laboratory experiment and proved by years of practical experience, is one which is well adapted to proper control by the licensing authorities. The flow of milk through the apparatus is required to be totally arrested for a period of not less than thirty minutes at a temperature of not less than 145° F. Both time and temperature afford ample margins of safety. Nevertheless, the control of apparatus designed to conform to the excellent official requirements demands knowledge, skill, and diligence from the representatives of the licensing authorities. That these have not always been forthcoming has been revealed by the phosphatase test.

What, then, is the reaction to the new Order? The holder type of plant occupies much space, requires much metal, is difficult to clean, and is necessarily rather inflexible in operation. Existing plants are wearing out and must be replaced, and the difficulties of operation imposed by war conditions are great. But the safety of the milk supply is more than ever necessary. These considerations have avowedly prompted the Minister to sanction the use of apparatus which occupies little space, is easy to clean and maintain, and is notable for its flexibility—all of which are desirable attributes in war-time. Further, there is evidence that the H.T.S.T. pro-

cess disposes efficiently of pathogenic organisms and that changes in the physical, chemical, and nutritive properties of the milk are, as in the holder process, minimal. The essential difference between this and the holder system is that at no time is the flow of the milk actually arrested. Moreover, the margins of safety, though similar on a relative basis, are less in terms of absolute time and temperature, and demand great precision in control. The Order requires that the apparatus shall be thermostatically controlled, fitted with an automatic device to divert milk which has not been properly heated, and furnished with such indicating and recording thermometers as the licensing authority thinks requisite. The licensing authorities must also decide on the suitability of the apparatus and thermometers used.

Much that is not categorically stated is laid on the licensing authorities, and it is clear that the H.T.S.T. process demands a well-informed and technically minded inspectorate. It will be necessary for them to recognize the lag of thermometers in responding to temperature changes, to bear in mind the mechanics of the flow of liquids through pipes, tubes, or their equivalents—the so-called "holder" section—to ensure the minimum holding time of fifteen seconds, and to be sure that the rate of flow of the milk through the machine, which determines the holding time, does not vary. Thermometers and recording apparatus must be checked against standard thermometers, and the considerations governing their positions in the plant must be appreciated. Great advances in the design of plant and control apparatus have been made in recent years and some of the essential parts of the newer apparatus are familiar to many, as they have for long been incorporated in holder machines. This, coupled with a substantial volume of satisfactory experience of the practical working of H.T.S.T. machines here and in America, goes far to allay any anxiety which may be felt as to the capacity of local authorities to implement the new Order.

The Order is provisional and the times are abnormal, but the safety of the milk supply must be assured. The advantages of the new system may well outweigh any apparent difficulties of administration and lead to important changes in the milk industry. Local authorities will no doubt take the steps necessary to dispel the doubts of those who maintain that licensing of plants should be in the hands of the central authority.

DIABETOGENIC ACTIVITY AND GROWTH

In 1937 F. G. Young¹ discovered that a short period of injections with anterior pituitary extracts induced in dogs a permanently diabetic condition—a condition he calls pituitary-diabetes. Later it was shown that the treatment caused changes in the islet tissue of the pancreas.² The findings served to explain the glycosuria which H. M. Evans and his colleagues³ found in some of their puppies treated with pituitary growth-promoting extracts, an observation not particularly stressed at the time and apparently not further investigated. In an important paper published elsewhere in

¹ *Lancet*, 1937, 2, 372.

² Richardson, K. C., and Young, F. G., *Lancet*, 1938, 1, 1968.

³ *Proc. Soc. exp. Biol.*, N.Y., 1931-2, 29, 877.

this issue Young has now brought forward evidence relating the growth-promoting and diabetogenic actions of pituitary extracts. The chemical properties of the two active extracts are similar, and Young's diabetogenic extracts have contained growth-promoting activity. In his first experiment he finds that injection of a pituitary extract which has diabetogenic activity in adult dogs did not produce glycosuria in puppies, even when given in more than six times the dose active in the adults; there was, however, considerable acceleration of increase in body weight. One of the puppies eventually developed glycosuria at a weight of 20 kg.; this is persisting at the time of writing. In a second series of experiments extracts which are diabetogenic in normal adult dogs and similar extracts which have lost their diabetogenic activity were injected into pituitary-diabetic dogs. These extracts were known to contain pancretrophic activity—that is, they cause an increase in the islet tissue and insulin content of the rat's pancreas. The results were not completely consistent, and the variations in response probably depended on the amount of undamaged islet tissue surviving in the pancreas of the pituitary-diabetic dogs. In some cases the severity of the diabetic condition was increased; in others it was ameliorated. These contrary results appear to be bound up with the nitrogen metabolism of the dog: when the diabetes is alleviated there are nitrogen retention and increase in body weight; when the condition is intensified there are increased nitrogen loss and fall in body weight. Growth-hormone preparations are known to induce nitrogen retention, and it is probable that this action is mediated by the islets of Langerhans.

An important aspect of the experiments lies in the clues they give to some of the factors in clinical diabetes. The majority of adult diabetics are over weight, and White has found that many diabetic children are above the average height. There is evidence that children have greater amounts of islet tissue in proportion to body weight than have adults, and if this condition holds in the dog the relative resistance of the puppies to diabetogenic extracts may be explained, the greater amount of islet tissue being sufficient for normal blood-sugar regulation, even in the presence of pituitary diabetogenic activity. Young puts forward the theory that slight pituitary overaction in the child may cause compensatory islet hypertrophy with nitrogen retention and growth; in the adult the same may occur, the stimulus increasing body weight but not being enough to cause skeletal changes. It is then suggested that the islet tissue may not be capable of maintaining this hypertrophy, so that lesions become predominant and the symptoms of diabetes follow. These suggestions and the evidence for them are considered in greater detail in the discussion in Young's paper, but enough has been said to demonstrate the possibilities of the hypothesis. Many cases of diabetes may therefore be caused by pituitary-pancreas imbalance rather than by primary pancreatic lesions. This suggestion obviously affords scope for future experiments, and it is to be hoped that Young will be able to continue his researches not only into the mechanism of production of diabetes but also into the vexed question of the nature and activity of the growth hormone. It may be noted that he is careful

to refer to "growth" in inverted commas, as his data at present only refer to changes in body weight, neither the components of this weight increase nor the skeletal changes having been determined in the present preliminary statement.

AETIOLOGY AND TREATMENT OF OSTEO-ARTHRITIS

In most cases osteo-arthritis is a degenerative process set up by repeated small injuries, often incurred during work. Once the cartilage has been even slightly injured the degenerative process progresses and causes steadily increasing disability; but in a large number of cases pain is not a conspicuous feature, and in consequence treatment is not seriously undertaken until the removal of the more obvious causes by change of occupation is likely to be of little effect. Magnuson¹ has carried out extensive experiments on dogs to investigate the changes that take place after slight injury to the cartilage and the mechanism by which they are produced. As an outcome of this work he has devised, and successfully performed, an operation in the human subject to which he has given the name "joint débridement." He has demonstrated that local areas of roughened cartilage may result from superficial injury which gradually progresses more deeply; or the degenerative process may begin in the matrix and gradually lead to fissuring and degeneration of the articular surface. Continual friction by the use of the joint leads to further damage round the original site and on the surface of the opposed cartilage. Magnuson has found it difficult to explain the causes of proliferation of bone round the edges of the joints—an important cause of limitation of the range of movement and often of pain—but he does not refer to the work of Corbin² at Stanford University, who obtained some interesting results by severing the lumbosacral nerve roots containing afferent fibres from the hip-joints. The resulting excessive range of movement and abnormal position of the joint led to erosion and fibrillation of the cartilage and to enlargement of the head of the bone and the acetabular cavity, apparently with the object of giving additional support to the limb. Pearson in 1928 produced evidence that degenerative changes take place in the posterior root fibres, as a result of arteriosclerosis affecting the column of Goll, the ability to perceive vibratory stimuli being thus diminished; it is suggested that the influence of arteriosclerosis in osteo-arthritis is exerted in this way and not directly through the blood supply of the joint, which Keefer and Myers have shown is not affected in proportion to the severity of the arthritic changes.

The operative procedure devised by Magnuson is to shave away the roughened areas completely and to remove all exostoses which may give rise to friction and interfere with the normal movements of the joint. The roughened surface being thus removed, the progress of the disease is arrested or at least delayed; the denuded areas become covered with fibrocartilage, which serves as a satisfactory substitute for the normal hyaline cartilage. Careful choice of patients is important; the full co-operation of the patient is essential. Special attention must be given to movement of the joint: this should be started on the fourth day after the operation and carried out under the close supervision of the surgeon. Magnuson has operated on sixty-two cases and has achieved good results in sixty; in the remaining two cases the patient did not co-operate and did not remain under his control. Although the number of cases is too small for exact conclusions to be drawn from this experi-

¹ *Surg. Gynec. Obstet.*, 1941, 72, 1.

² *Arch. Surg.*, Chicago, 1937, 35, 1145.

ence, the results appear to justify further trial in suitable cases of this distressing complaint. The time since operation in Magnuson's cases has varied from sixteen years to six months: it is obvious that if the operation is to be regarded as a success relief from symptoms, even if not permanent, should at least last for a period of years. It is probable that the best results will be obtained only in comparatively young subjects with clear evidence of repeated traumata as a cause, and that when there is evidence that arteriosclerosis is a contributory factor the results are less likely to be satisfactory.

CLASSIFICATION OF CROUP

Gilbert, Meyersburg, and Silverberg,¹ in analysing a series of 226 cases of croup admitted to the Kingston Avenue Hospital, Brooklyn, New York, call attention to the great decrease in the incidence of diphtheritic croup, whilst the number of cases of non-diphtheritic croup remains about the same. Before the use of diphtheria prophylactic and antitoxin 60% of the cases were diphtheritic, but in the series under review observed during one year the incidence of diphtheria was only 7%. The authors apparently assume that this remarkable change in incidence is due entirely to protective immunization, for they make no comment on the possibility that other factors may also be concerned. The analysis is therefore chiefly related to the non-diphtheritic group, for which a varied and consequently confusing nomenclature has evolved. The authors propose the following classification: (1) diphtheritic croup—(a) diphtheritic obstructive laryngitis, (b) diphtheritic obstructive laryngo-tracheitis, (c) diphtheritic obstructive laryngo-tracheo-bronchitis; (2) acute catarrhal laryngo-tracheitis; (3) supraglottic oedematous obstructive laryngitis; (4) subglottic obstructive laryngitis and tracheitis—(a) subglottic exudative obstructive laryngitis and tracheitis, (b) subglottic oedematous obstructive laryngitis and tracheitis; (5) acute obstructive laryngo-tracheo-bronchitis; (6) unclassified, due to allergy, foreign body, and chemical irritants. For diphtheritic croup the authors recommend in general 20,000 units of antitoxin intramuscularly and 10,000 units intravenously. Laryngoscopic suction is employed when it appears indicated. In the severe form of diphtheritic obstructive laryngo-tracheo-bronchitis tracheotomy is required and suction is carried out by passing a bronchoscope through the tracheotomy wound. The two patients with such condition in the series treated in this way both recovered.

Turning to the large non-diphtheritic group the authors draw special attention to the supraglottic oedematous obstructive laryngitis, in which the swelling affects the epiglottis and aryepiglottic folds. Tracheotomy is indicated in preference to intubation, for the swollen mucous membrane overlaps the upper end of the intubation tube and blocks the airway. All the six patients in the series treated by tracheotomy recovered. The authors believe that supraglottic and subglottic oedema rarely, if ever, occur together. For the subglottic obstruction laryngoscopic suction is recommended, and they advise tracheotomy in preference to intubation in all cases in which suction is not sufficient to provide relief. Acute obstructive laryngo-tracheitis and acute obstructive laryngo-tracheo-bronchitis must be distinguished from pneumonia by the physical signs indicating obstruction. Acute obstructive laryngo-tracheo-bronchitis, however, has a high mortality, but is treated on the same lines as the other forms of croup, in which the prognosis is good. The authors have very little information to offer on the bacteriology or chemotherapy of the conditions discussed.

SOLAR URTICARIA

In contradistinction to sunburn, which is solar erythema and very common, urticaria as a result of exposure to sunlight is very rare. Several cases, however, have been described, the first of which appears to have been that of Duke in 1923. He studied this case in some detail and suggested the name "urticaria solaris" for the condition. His patient was a woman aged 43 who had been affected four years. Duke was able to reproduce the lesions by sunlight filtered through colourless or violet glass and also by electric light. X rays were ineffective. He thought that the spectral region responsible was the visible portion together with the far red and infra-red. A good many cases have been described since that time and rough attempts have been made with filters of various colours to determine the part of the spectrum which is to blame for the manifestation. But the use of filters is full of pitfalls for the unwary, for many filters have broad transmission bands well outside the spectral range that their colour suggests. The one readily available "cut-off" filter which can be relied on is ordinary window glass. It absorbs almost all wave-lengths shorter than about 3,200 Angstrom units—that is, almost all the ultra-violet region. Dr. Arnold² of Hawaii had the opportunity of studying a case in some detail in a young man of 26 who, when he came under observation, had been subject to the condition for some five years, although owing to the patient's early departure the investigations could not be completed. His reaction to sunlight filtered through window glass was just as severe as to direct sunlight, but he was not at all sensitive to light from the air-cooled quartz mercury vapour lamp. He was also very little sensitive to photoflood lights, which include much red and infra-red, or to the carbon arc lamp, which includes much violet and ultra-violet. These observations seem extremely difficult to explain. More information was obtained from the study of filter data. To epitomize the results of these investigations, it may be stated that the maximum response was elicited from radiation of wave-length from 3,800 to 5,000 Angstrom units, but all the same the four mercury lines in and adjacent to that region must be ineffective, or there would be a response to the mercury vapour lamp. No response at all was obtained from irradiation through the Wratten green gelatin filter of thirty minutes' sunlight. This filter transmits not only green but the entire infra-red portion of the spectrum, and these regions must therefore be exonerated. It appears probable that the effective rays are to be found in the blue and violet regions, but their exact position cannot be clearly defined.

At the last Court of Governors of the Middlesex Hospital Sir Alfred Webb-Johnson was elected a Vice-President of the hospital. The Court desired to recognize not only his election as President of the Royal College of Surgeons but also his invaluable services in the planning and rebuilding of the hospital, and in the raising of so large a part of the sum required for the reconstruction scheme. This is the first occasion on which this honour has been conferred upon an active member of the honorary staff.

We regret to announce the death of Dr. Robert Dawson Rudolf, C.B.E., F.R.C.P., emeritus professor of therapeutics in the University of Toronto and consulting physician to the Toronto General Hospital and Sick Children's Hospital. Dr. Rudolf during the last war was consulting physician to the Canadian Forces in England with the rank of Colonel C.A.M.C.

REGIONAL HOSPITAL SERVICES POLICIES OF NUFFIELD TRUST AND B.H.A.

The British Hospitals Association has issued a "Memorandum of Policy on Regionalization of Hospital Services," although the uncouth word "regionalization," as it explains, is to be dispensed with so far as possible in favour of the term "co-ordination." The memorandum was prepared before the Minister of Health's statement in the House of Commons on October 9 defining the Government's post-war policy on hospitals, but no amendment has been found necessary. The document is really a postscript, although a very substantial one, to a pamphlet by the Nuffield Provincial Hospitals Trust on "The Co-ordination of Hospital Services," which should be read first.

The Nuffield Trust, founded two years ago, has for its object the co-ordination on a regional basis of hospital and ancillary medical services throughout the Provinces, Scotland, Wales, and Northern Ireland. For the London area, so far as voluntary hospitals are concerned, the King Edward's Hospital Fund serves as a central financial organization. The Voluntary Hospitals Commission, under Lord Sankey, recommended the division of the country into regions, with a council in each region to correlate hospital work. The necessity was recognized for co-ordination not only between voluntary hospitals themselves, but between voluntary and municipal, if overlapping was to be avoided, the best use was to be made of available accommodation, and consultation was to take place before new services were started. With these considerations in mind Lord Nuffield created and financed the Trust. During the last eighteen months preliminary conferences have been held in many large centres, and a number of regional or divisional councils have been formed or are in process of formation.

General Medical Policy of Nuffield Trust

A statement by the Medical Advisory Council of the Nuffield Trust—a council which comprises twenty-four leading representatives of medicine under the chairmanship of Sir Farquhar Buzzard—is embodied in the Trust pamphlet. The Council points out that the problem facing each region is, while centralizing the more expensive and specialized methods of investigation and treatment at the larger hospitals, to ensure that these are accessible in case of need to every practitioner and patient within the region. The small and scattered hospitals must be linked up, by visits from the consulting staff and in other ways, with the "key" hospital (meaning by the latter teaching hospitals or, in divisions where there are no medical schools, large non-teaching hospitals). Such linkage will be one method of bringing the general practitioner into closer contact with the "key" hospital.

The distribution of consultants and specialists in the new or future "regions" has been unequal. In some areas it may be advisable for consultants, while nominally on the staff of the "key" hospital, to reside in an outlying area and serve a group of small hospitals. Perhaps medical appointments may be made, not to individual hospitals, but to a region or group of hospitals within a region, so that each member of the staff may eventually carry out the work for which his abilities and experience most suit him, whether general consulting practice, one of the specialties, teaching, or research.

The findings of the Interdepartmental Committee on Rehabilitation, published in 1939, have the approval of the Medical Advisory Council, but fracture services in themselves are not considered to be enough; what is needed is an "accident service" organized regionally to treat not only fractures but lacerations and contusions, burns and scalds, and sepsis as a result of injury.

As for pathological services, these in the large teaching hospitals leave little to be desired, but in the country as a whole they fall far short of requirements. The Council urges that

existing laboratory facilities should be co-ordinated on a regional basis, which would increase their efficiency in various ways, enabling any laboratory within the region to have in a consultative capacity the services of a highly skilled bacteriologist, morbid anatomist, or other expert. It sets out certain conditions to be secured in the administration of pathological services, the principle being that all such work should be done by pathologists attached to public health laboratories, hospitals, or university departments; that all clinical pathology should be done by pathologists working in hospital laboratories; and that in each region or division there should be at least one public health laboratory concerned mainly with epidemiological work and co-operating in that field with medical officers of health and general practitioners.

How Regions are to be Determined

The British Hospitals Association in its complementary memorandum states its entire agreement with the principles of co-ordinated hospital services as described by the Nuffield Trust. The Association has had its own regions and regional committees, but to avoid confusion it is renaming them "areas," their boundaries to be so far as possible coterminous with those of the "divisions" or parts of regions through which co-ordination will be developed locally. Close contact between the B.H.A., the Trust, and King Edward's Hospital Fund has been ensured by arrangements for representatives of each body to sit on the councils of the others.

In proceeding to effect co-ordination the local area committee of the B.H.A.—which represents voluntary hospitals only—if it feels that local conditions are favourable, will invite representatives of the local authorities to a preliminary conference and proceed to a detailed examination of a scheme, not overlooking contiguous areas. Alternatively the Nuffield Trust may, after consultations, take the initiative of calling a preliminary conference to which representatives of both voluntary hospitals and local authorities will be invited. The voluntary hospitals as such will from time to time have a policy or unanimous view to express, and this can be done through the area committees; the regional council consists of municipal as well as voluntary representatives.

It is fully recognized that it is not competent for voluntary hospitals alone to determine areas; the views of local authorities are of at least equal importance. Nor must areas be considered as surrounded by a Chinese Wall or unbreakable barriers; a region or division is merely a unit formed after taking into consideration a number of factors, such as the nature of the hospital services generally available. It is not desired to interfere with the freedom of the patient in his choice of doctor or of the doctor in his choice of hospital or consultant. The unit must be formed naturally, and in its formation there will be no compulsion on a particular hospital.

There are hospitals which are apprehensive of co-ordination as threatening their existence or development.

... Co-ordination does not mean the domination of the unit by one centre; it does not mean a concentration of all the specialist services at, for instance, a teaching hospital and the reduction of all other hospitals in the region to a secondary standing; but on the other hand it does mean the improvement and the maintenance of an adequate standard of services in the region or division.

This may be accomplished in some cases by concentrations of services, in others by dispersal.

Again, the regional and divisional councils are essentially advisory bodies, or are executive only to such extent as powers are given to them unanimously by their constituents. Co-ordination, in fact, is a reciprocal matter between voluntary hospitals and agencies on the one hand and local authorities on the other. It calls for mutual understanding and confidence and a pooling of knowledge and facilities.

H. R. Russell and R. C. Page (*Amer. J. med. Sci.*, 1941, 202, 355) point out that, as vitamin K belongs to the group of fat-soluble vitamins, it should be absorbed through the skin. Accordingly they applied 10 milligrammes of synthetic vitamin K analogue in an ointment base to a series of newborn infants. A single application was found to be effective in preventing hypoproteinaemia.

AWARDS FOR GALLANTRY

The awards of the M.B.E. (Civil Division) to Dr. William Louis Murray Bigby, assistant medical officer of health for civil defence, Southampton, and to Dr. John Findlay, doctor in charge, first-aid post, Civil Defence First-aid Post Service, Peterhead, and the B.E.M. (Civil Division) to Mr. R. A. Gow, caretaker, Civil Defence First-aid Post Service, Peterhead, are announced in the second *Supplement* to the *London Gazette* dated December 12. The announcements read as follows:

Dr. Bigby: Dr. Bigby has been on duty throughout the period of air raids on Southampton. He has worked long hours helping to extricate trapped people, and on several occasions has entered wrecked buildings in order to relieve the sufferings of the injured. He has shown courage and qualities of leadership without regard to his own safety."

Dr. Findlay and Mr. Gow: "A high-explosive bomb demolished a building, and members of a first-aid post were injured and trapped. Dr. Findlay was thrown to the floor and injured, but despite this, at grave risk to himself, he crawled under the loose debris and gave injections to three casualties. He then organized the removal of the post to a temporary site, where he again took charge. Dr. Findlay showed qualities of leadership, courage, and devotion to duty, and in his work of rescue was helped by Mr. Gow, who, although badly shocked, courageously worked with the doctor for two hours, searching for the injured men."

Reports of Societies

WARTIME RATIONING AND CHILDREN'S HEALTH

At a meeting of the Section for the Study of Disease in Children (Royal Society of Medicine) on November 28, with Dr. A. G. MAITLAND-JONES in the chair, a discussion took place on the effects of wartime rationing on child health.

Dr. E. M. WIDDOWSON mentioned a dietary survey carried out during the years 1935-9 on 1,000 individual middle-class children, the data of which had since been re-analysed to show the effects that rationing must have had on the diets of these children. The pre-war consumption of most foods, whether now rationed or unrationed, was found, as might be expected, to rise with increasing age. A comparison of the intake before the war of foods now rationed with the actual rations to-day gave an idea of what the changes must have been. Up to the age of 6 children with the green ration book got half the adult allowance, and from then onwards the full adult ration. Up to the age of about 8 children were just as well off in respect of butcher's meat as before the war, but boys of 15 before the war were eating about three times as much meat as they were now allowed. The average boy was also eating before the war about twice as much sugar as now. Butter was much reduced in the child's wartime dietary, but the position was different with regard to cheese, which was eaten by only a small proportion of children in pre-war times. If the child below 8 was eating the whole of his rations he was just as well off as before the war, except for butter; the child over the age of 8 was not as well off, and adolescents had had to make a big change in their dietary habits. All this was on the assumption that the rationing system was rigidly followed, whereas, of course, in the ordinary family it would not be, the older children probably receiving larger helpings of pudding made with the family's sugar and jam ration, and in boarding schools for children of 14 to 18 the effect of rationing was probably most markedly seen. Milk had only just begun to be severely restricted, but children were in a priority group, and with the help of school milk might get, until leaving school, even more milk than they got before the war. The children who suffered most were those who left school at 14, when calcium requirements were at their maximum. The availability of vitamin C was reduced, not on account of rationing but because of the scarcity of fruit. Scurvy, however, did not seem to have appeared.

Recognition of Dietary Deficiency

Dr. D. C. WILSON said that it was important to appreciate the difference between examination for signs of malnutrition carried out during routine school inspection and the use of growing children as indicators for the detection of signs of dietary deficiency within a community. During medical inspection the state of nutrition was assessed according to the standards laid down by the Board of Education. Such examination was useful in drawing attention to the many different causes in home and school life which might adversely affect the child's well-being, and thus permitting the application of the appropriate remedy. For the early detection of specific dietary deficiency within any group special tests were necessary, and these, applicable under wartime conditions in English schools, were described.

Dr. HELEN MACKAY said that it must not be supposed that because a child's ration had been calculated he would get it, and that there was no need to look for deficiency disease. Distribution was often far from ideal. A great deal depended on whether the people who looked after the children knew the best substitutes for food in short supply and how to use them. There was a general impression among paediatricians and in the public health services that tuberculosis had increased. One could only guess how much of this was due to the wholesale discharge of cases at the beginning of the war, how much to the consumption of unboiled tubercle-infected milk by evacuated city children accustomed to pasteurized milk, and how much to deficient diet. She emphasized the importance of looking for objective evidence in deficiency diseases; the subjective classification in many public health reports seemed utterly useless. There was some increase of rickets last winter, but she had not seen any signs of scurvy in her clinic, nor any increase in angular stomatitis or conjunctivitis. The proposal for well-balanced school meals should be supported. Something ought also to be done for mothers of young children, who probably suffered from giving away their rations.

Vitamin C Deficiency in Children

Dr. W. W. PAYNE said that children at a base hospital in the spring of 1941 were examined by a single saturation test and found to be uniformly deficient. The hospital diet was very inadequate in vitamin C and was estimated to give only 6 mg. of ascorbic acid a day with average helpings of vegetables. Supplements of 50 mg. ascorbic acid daily for fourteen to twenty-one days failed to saturate. On giving the full saturation dose (50 mg. ascorbic acid per stone daily), it was found that only fourteen out of twenty-seven became saturated within three days. In seven of these the failure to saturate was probably due to the illness. Thus six of the twenty-seven children tested were very deficient in vitamin C, having an approximate deficit of 1,000 mg. of ascorbic acid. Once these children were saturated it was found that a dose between 20 and 40 mg. a day sufficed to keep them so. Certain non-febrile diseases appeared to require more ascorbic acid—for example, chorea, ulcerative colitis, and coeliac disease.

Dr. J. A. GLOVER said that the school child at the beginning of this war was in far better condition than his predecessor in 1914—bigger, better nurtured, better clad, cleaner, and more resistant to infection. It was impossible to disentangle the effects of rationing from those of many other abnormal factors which influenced wartime health and nutrition, such as evacuation, closing of schools, and shelter life. The most reliable evidence against deterioration was the opinion of the great majority of school doctors, nurses, and teachers. The decreased incidence of infectious diseases might also be regarded as evidence against deterioration. There was a temporary increase of scarlet fever and diphtheria in the last quarter of 1939, but it died away very rapidly. Tuberculosis had possibly increased to some extent, but his impression was that the incidence of acute rheumatism and chorea had somewhat decreased.

Dr. H. P. BAYON spoke of the importance of iron in the nutrition of children. The greatest trouble in practice was the weaning period, with lack of eggs and oranges and unreliable supplies of cod-liver oil. It was not enough to have the requisite iron or vitamins in the food if the food was not

easily assimilable. Palatability had to be considered along with nutrition.

Prof. A. St. G. HUGGETT said that if the mother during pregnancy were on a short diet the child would benefit at the expense of the mother at first, but if the shortage continued the child also would be affected and show anaemia after birth. From certain records of infants born during the first six months of the present year there appeared to be some loss of weight. It was likely that infants would show less resistance to disease unless the mother's diet during lactation could be kept well up to requirements. With regard to vitamin C, ascorbic acid tablets were not a good substitute for fresh vegetables. Bread became more important with the cutting down of milk, but unless something were supplied to lubricate the bread the right quantity for the pregnant woman would not be taken, and both she and the child would suffer.

MODE OF ACTION OF CHEMOTHERAPEUTIC AGENTS

The Biochemical Society held a discussion meeting on the mode of action of chemotherapeutic agents on November 29 at the Courtauld Institute of Biochemistry, Middlesex Hospital, Prof. E. C. DODDS being in the chair.

General Principles

Dr. G. M. FINDLAY, in opening the discussion, said that chemotherapeutic action might be classified as direct or indirect. Except in the case of parasites present in the intestinal canal it was essential that the chemotherapeutic drug should be absorbed into the body, that it should penetrate to the site where the parasites were acting, and that it should not be excreted or converted too rapidly into an inert form. Time must be allowed for chemotherapeutic action and, in some cases, for the conversion of the compound from an inactive into an active form.

When once the drug and the parasite had been brought face to face three stages might be distinguished—adsorption, interference with metabolism, and death or such injury to the parasite that it was destroyed by the phagocytes of the host. An adsorbed chemotherapeutic drug might prevent an essential food factor from being absorbed, or it might cause a breakdown in metabolism by combining with a specific substrate or by competing with an essential cell metabolite for an enzyme or coenzyme. One break in the chain of metabolic reactions might rapidly give rise to others. Specific immune serum and sulphapyridine did not compete for the same receptor group in the pneumococcus and might therefore enhance one another. Parasites might be killed in the body without the aid of phagocytes, but usually when a parasite had been damaged it was destroyed by the normal defence mechanism of the host.

Indirect action produced such changes in the environment that parasites could no longer grow. Physical changes might prevent growth, the temperature or the pH reaction be altered, the formation of immune bodies stimulated, or the character of the cells altered, as in the treatment of gonococcal vulvovaginitis in children with oestrogen preparations. The highly specific action of certain drugs, and the no less specific reactions of certain closely allied parasites, could be explained by postulating that after adsorption of the compound at the parasite-solution interface the nature of the interference with the metabolism of the parasite depended on what groupings in the molecule of the compound came within the influence of other acceptor groups in the parasite: there was thus a multi-point action.

Penicillin

Prof. A. FLEMING, continuing the discussion, said that in 1929 he had applied the name "penicillin" to an antibacterial substance of unknown constitution elaborated by *Penicillium notatum* when grown in ordinary bacteriological media or in a modified Czapek-Dox medium. The action was mainly bacteriostatic and showed a high degree of specificity. Pyogenic cocci, clostridia, and some other bacteria were sensitive, while the coli-typhoid, haemophilic chromogenic bacilli, and others were insensitive. Pathogenic Gram-negative cocci (gonococcus,

meningococcus, and *M. catarrhalis*) were sensitive, while saprophytic varieties (e.g., *M. flavus*) were, insensitive, penicillin thus differing from the sulphonamides.

The action of penicillin was not interfered with by substances that inhibited sulphonamides—bacteria, bacterial extracts, pus fluids, tissue autolysates, peptones, and *p*-aminobenzoic acid. Penicillin was non-toxic to leucocytes and animals, but in low dilutions it affected the morphology of bacteria and interfered with division. As penicillin and also gramicidin were apparently of a different constitution from the sulphonamides, the isolation and synthesis of the pure active principles would open up a new chemotherapeutic field.

Trypanocidal Drugs

Prof. WARRINGTON YORKE described the action of the aromatic diamidines which were evolved by Dr. Ewins, after it had been shown that synthalin (decane diguanidine) acted on trypanosomes not by reducing the sugar but by direct toxic action. Some aromatic diamidines exhibited a remarkable trypanocidal activity. The most active were 4:4'-diamidino-stilbene, 4:4'-diamidino-diphenoxy-propane, and 4:4'-diamidino-diphenoxy-pentane. Cases of kala-azar had now been successfully treated by diamidino-stilbene—Indians, children in the Mediterranean area, and patients with the Sudanese variety, which was resistant to antimony. Babesia infections in dogs were cured by the stilbene and propane derivatives, the stilbene being highly active against *Trypanosoma congolense*. The compounds had a highly specific action. Drug resistance appeared to be due to a change in the surface layer of the parasite. Trypanosomes resistant to a number of compounds had now been prepared, including a diamidine preparation. It had also been possible to prepare a diamidine-resistant *Babesia* and a plasmoquine-resistant strain of *Plasmodium knowlesi* in the monkey.

Dr. F. HAWKING, discussing trypanocidal substances, said that from the phenomenon of drug-resistance four kinds of receptors on the trypanosome were recognized. Trypanocidal action comprised fixation of the drug, secondary chemical reactions inside the cell, and death. Only about the first process was much known: it occurred quickly in a few minutes and was reversible. With arsenical compounds fixation apparently depended on the trivalent arsenic atom linked to a benzene ring. Certain side chains ($-NH_2$, $-OH$) prevented fixation on animal cells but not on normal trypanosomes; the receptors of resistant trypanosomes were modified. Over a wide range the amount of drug fixed was proportional to the concentration in the surrounding fluid; in the case of acriflavine the partition ratio—concentration inside the trypanosome/concentration outside—was 8,000 for normal trypanosomes, 60 for resistant trypanosomes. Fluorescent compounds, acriflavine, and diamidino-stilbene were concentrated in the blepharoplast and cytoplasmic granules of the trypanosome.

Ehrlich's Theory

Sir HENRY DALE, after congratulating the Society on arranging a discussion meeting in wartime, emphasized the importance of having a theory of chemotherapeutic action. It was one of Paul Ehrlich's great contributions to the subject to have produced a theory which, though it would probably not survive unmodified, had given a tremendous stimulus to research. His speculations had sometimes appeared more plausible than convincing; but it was remarkable in how many cases they had eventually proved to be well founded. An example was Ehrlich's explanation of the action of certain dyes on infection by trypanosomes as due to injury of the reproductive power of the trypanosomes without affecting their other vital functions. At the time this suggestion seemed artificial and unconvincing, but when Dobell and Laidlaw found a method for growing *Entamoeba histolytica* in permanent culture *in vitro* it could be demonstrated that the action of emetine was just of this type. Another factor of chemotherapeutic activity which he believed to have importance was the "factor of persistence."

Effective chemotherapy was usually, if not always, a war of attrition rather than a "Blitzkrieg." This seemed to be the reason why a quinquivalent arsenical on the one hand, or an arseno-compound on the other, was a better chemotherapeutic agent than the arsenoxide produced by reduction from the one

or by oxidation from the other, although the arsenoxide was recognized as the directly parasitocidal agent. In the same way, sulphaguanidine seemed to owe its effectiveness in bacterial dysentery to its poor solubility, enabling it to remain in solid form in the intestinal contents and to keep up a steady, low concentration in contact with the infected mucous membrane. Aromatic diamidines, the brilliant promise of which had been made clear by the results which Prof. Yorke had reported, might similarly owe part of their superiority to their limited solubility. He ventured to suggest as problems the solution of which might greatly accelerate advance in parts of the field of chemotherapy, the discovery of a method of keeping trypanosomes alive and reproductive indefinitely in artificial culture, and the discovery of a method of treating a strain of trypanosomes which had acquired drug-resistance, so as to restore the normal susceptibility.

Some Modern Observations

Dr. D. D. Woods spoke of the interference of antibacterial agents and essential metabolites. This interference might be due to the formation of a compound between the antibacterial agent and the essential metabolite, as between mercury salts and $-SH$ compounds, or by inhibition of an enzyme reaction involved in the synthesis or utilization of an essential metabolite. An example of this was the competitive inhibition by sulphanilamide of an enzyme reaction involved in the further utilization of *p*-aminobenzoic acid, this inhibition occurring by virtue of the chemical relationship of sulphanilamide and *p*-aminobenzoic acid. The latter had been isolated from natural sources and was a growth factor for *Clostridium acetobutylicum* and higher organisms. On this hypothesis the following substances, all chemically related to a known essential metabolite, the latter shown in parentheses, were found to have some antibacterial activity: pyridine-3-sulphonic acid and amide (nicotinic acid and amide); aminosulphonic acids (analogous aminocarboxylic acid); sulphonic acid analogue of pantothenic acid (pantothenic acid); indole-3-acrylic acid (tryptophan); barbituric acid (uracil).

Dr. H. McLWAIN said that an organism which was deprived of the use of enzymes or metabolites by various types of interference was nutritionally more exacting than in its normal state. *Bact. coli* and *Str. haemolyticus*, inhibited by acriflavine components, required for further growth two types of material not normally required. Type I was best replaced by nucleotides; Type II by a concentrate of amino-acids, but partly by phenylalanine. In the presence of Type II compounds, but not without, artificial hydrogen carriers were further active against inhibition of *Bact. coli*. Type I compounds formed complex salts with acriflavine components. The inhibitors probably inactivated enzyme systems of which Type I compounds were essential parts, of which Type II compounds were substrates or products, and of which some could be replaced by the hydrogen carriers.

Dr. W. H. LINNELL described the relation between chemical constitution and bactericidal action in certain amino-acridines. Among the isomeric diamino-acridines, a 1-amino group caused complete loss of bactericidal activity and reduced toxicity; a 2-amino group increased activity, and this was further enhanced by another amino group in the 2-, 3-, 4- (in the other ring), or 5-positions, accompanied by increased toxicity in the case of a second 2-substituent. When two 3-amino groups (=3:7) were present activity was moderate, but the 3:8-diamino-acridine (=2:7) was as active as proflavine but less toxic. A 4-amino substituent conferred small activity, while position 5 was highly active but probably led to increased toxicity. Albert had shown that similar differences in activity existed among the five isomeric mono-amino-acridines, their activity paralleling their strength as bases and their partition coefficients between oil and water. The corresponding acridones were inactive, as were certain amino derivatives of 5:10-dihydroacridine and of iminodihydroacridine, suggesting that the intact acridine molecule was necessary.

Mr. L. G. GOODWIN said that the uncertain action of antimony in protozoal diseases, of which the resistance of Sudanese kala-azar to antimony was an example, was an added difficulty in investigating its mode of action. The active form of antimony might be the stiboxide grouping, but while this was

probable in trypanosome and schistosome infections, it was unlikely in leishmaniasis, where quinquivalent compounds were the most effective and massive dose therapy was successful.

Excretion of antimony after doses of the quinquivalent compounds or of stibophen was much more rapid than with tartar emetic. There was some indirect evidence that the rapidly excreted fraction of the drug passed through the body unchanged. Both direct toxicity action on parasites and stimulation of the host's defence mechanisms were produced by antimonials. Increased phagocytosis might be of primary importance in leishmaniasis, though histological work on the spleens of infected hamsters injected with a quinquivalent antimony compound suggested some degree of direct action.

Dr. E. CHAIN described the chemical and physical properties of penicillin in relation to its bacteriostatic action. It is a strong acid with two, or a multiple of two, acid groups. A purified barium salt gives a carbon content of 55% and an H content of 6.3%: only C, H, and O are present in the molecule. Methoxyl groups cannot be detected, but two hydroxyl groups are present. The dried Ba salt of penicillin keeps indefinitely, and in watery solution is most stable between pH 5 and 7. With heavy metals, except Fe^{+++} , it forms water-soluble salts. The antibacterial action is lost by oxidation with hydrogen peroxide and potassium permanganate. Dr. E. P. ABRAHAM said that the instability of penicillin necessitated three methods of purification dependent on distribution between solvents, adsorption, and reduction. The crude barium salt obtained from an amyl acetate extract of the medium has an activity of 15 to 25 units per mg. Distribution between water and ether at pH 2 and pH 6, adsorption of impurities by charcoal, and chromatographic analysis on alumina yield a light yellow barium salt with an activity of about 150 units per mg. On reduction of this material in neutral solution with aluminium-mercury couple, the remaining pigment is adsorbed by alumina. The white barium salt obtained from the supernatant has an activity of 240 units per mg. It completely inhibits staphylococcus in a dilution of 1 in 5,000,000, partially in a dilution of 1 in 16,000,000.

Dr. F. R. BRADBURY had studied the behaviour of sulphanilamide, *p*-aminobenzoic acid, and chemically related compounds, aniline and sodium benzenesulphonate, at the surface of *Bact. coli* by electrokinetic methods. The shapes of the curves relating variation of mobility with time of contact for sulphanilamide and *p*-aminobenzoic acid were quite different from those of the curves for aniline and sodium benzenesulphonate. The curves for sulphanilamide and *p*-aminobenzoic acid were similar, suggesting that the two compounds behaved in a like manner at the bacterial surface.

Prof. A. ST. G. HUGGETT said that dyes such as chlorazol sky blue F P S (Chicago blue) and chlorazol fast pink B K S were excellent anticoagulants. Structurally they resembled afridol violet, from which Bayer 205 was derived; they had a trypanocidal action, while Bayer 205 had an anticoagulant action. The dyes acted at two points in the clotting mechanism as antikinase and antithrombin. Their anti-enzyme action with blood clotting might have an analogy to their mechanism as trypanocidal agents.

PLANNING IN THE FEVER SERVICE

The Fever Hospital Medical Service Group of the Society of Medical Officers of Health met last month at B.M.A. House to consider the position of infectious diseases hospitals and of pathological services in post-war planning.

Fever Hospitals

Dr. H. STANLEY BANKS (L.C.C.), who opened the discussion, thought that fever hospitals as well as general hospitals should be regionalized. Modern fever hospital work required the equipment of a general hospital—for example, first-class laboratory service, x-ray department, operating theatre, and physiotherapy. Experience showed that wards for the "general sick" could quite well be a success in fever hospitals. In future fever units and general units should be combined under one administration. He pointed out that over 80% of fever hospitals, excluding those in London, had fewer than fifty beds.

and about 55% fewer than twenty beds. Many of these small hospitals should be either closed or linked up with others. It was of first importance to determine the best method of administration of a regional authority. The usual local authority method by which a chief medical officer appointed by the authority was responsible for both the management and medical direction inevitably led to a centralized bureaucracy. This might be efficient for a time by improving the backward units, but soon failed because of the atrophy produced at the periphery. Medical progress depended primarily upon the maintenance of initiative at the periphery and secondarily upon support from the centre. There should be a proper balance of power and responsibility between the two. This might be done by leaving medical direction in the hands of local and regional medical committees of senior staff. The regional committee could make itself responsible for conveying all necessary medical advice and direction to the authority, by the use of a whole-time staff if necessary. Some such scheme of decentralization of medical direction was essential to preserve the vitality of a hospital service.

Dr. L. J. M. LAURENT (L.C.C.) suggested that voluntary hospitals, owing to increasing grants from the State, were bound to come under State control. They enjoyed a semi-independence which helped medical progress but did not further mutual support. Municipal hospitals under the management of local authorities had become as efficient as voluntary hospitals, but laboured under a highly centralized administration. Any future scheme of hospital planning should avoid the disadvantages of both, and also especially avoid the perpetuation of a dual system of hospitals. The creation of a regional authority which would control both kinds, treating them as equal partners, would be a step in the right direction. A unified system of national hospitals might eventually be achieved. Modern fever hospitals approximated so much to general hospitals that they should naturally come under the same authority in any future scheme. Small fever hospitals should be replaced by larger units serving adjacent areas. As a result of the war the large fever hospitals were now treating cases of tuberculosis, chronic sick and senile patients, pneumonias, skin disorders, and casualties, besides cases of notifiable disease. After the war a diminution of infectious diseases was to be expected. The beds left vacant could no doubt be utilized for the treatment of cases similar to the above. For the needs of medical education they should be allowed to receive fever patients from larger areas than at present. The building of an infectious diseases block attached to a general hospital would be of mutual benefit to both sections.

Dr. A. A. CUNNINGHAM (L.C.C.) thought that much of the open-ward accommodation in large fever hospitals could be made available for general medical and surgical cases. This practice was initiated in London before the war. The head of a hospital should be a medical superintendent, not a layman, but there should be well-paid posts for good clinicians. Teaching hospitals should have a voice in the appointment of those who trained students in infectious diseases.

Pathological Services

Dr. J. E. MCCARTNEY (L.C.C.) said that a pathological service must provide for all classes—not only for hospitals but also for medical practitioners and public health work. It was essential to have the laboratory as near the patient as possible; therefore the technical work should be decentralized as much as possible. On the other hand, it would be advantageous to centralize and standardize, so far as practicable, supplies, equipment, conditions of service, etc. The country would be divided into a number of regions, defined geographically and according to population and existing facilities, each of which would be an administrative entity. The regions would be divided into groups each under a group pathologist, situated in the main laboratory of the group. A group laboratory would be similar to an L.C.C. group laboratory, adequately staffed and equipped. According to requirements there would be subgroup laboratories staffed by assistant pathologists, and where work was insufficient for a medical staff a technician would be employed. No separate public health laboratories as such would be provided, but the medical officer of health would be in touch with the group pathologist in his area, who would arrange for all patho-

logical work. If epidemics occurred it would be possible to bring the laboratory to the epidemic by means of a mobile laboratory staffed by personnel from less busy parts of the region. The pathological work of the region would be co-ordinated by a regional pathologist, who should not be a whole-time administrator but attached to or in charge of a laboratory, and whose work would be mainly technical. All regions would be co-ordinated by a director of pathological services. Technical and administrative sides would be run by a committee consisting of regional pathologists and administrative staff—for example, for personnel, finance, buildings, etc. Thus the whole country would have a pathological service, co-ordinated and correlated. London would be organized on similar lines to suit its particular requirements. The L.C.C. Pathological Service now functioned as a regional laboratory service with its group and hospital laboratories, centralization of supplies, and administrative services. He suggested that this service should be the basis of a national one. As regards teaching, there should be full co-operation with University teaching departments, many of which would be the main regional laboratories.

Dr. R. CRICKSHANK (L.C.C.) thought that the establishment of laboratory services in close association with infectious diseases hospitals needed to be greatly developed, for laboratory help was essential in the diagnosis, treatment, and control of most infectious diseases. Besides, a laboratory *in situ* helped to maintain a high standard of work in the hospital and encouraged co-ordinated investigation and research. For the proper discharge of this last function the laboratory staff must not be overburdened with routine work, and, more important, the intellectual calibre of the personnel should be high. In the past the clinical pathologist had often been regarded as inferior to his colleagues in the teaching and research departments, but with full-time adequately paid posts and encouragement of research clinical pathology should be able to attract the best brains to its service. The laboratory doing the bacteriological work of the infectious diseases hospital should also do the public health bacteriology of the surrounding area. Such an arrangement seemed specially desirable in the London area, where the liaison between the borough M.O.H. and the local isolation hospital was not as close as it might be. Field epidemiology, at present rather neglected, would also be encouraged by a system of regional laboratories such as the L.C.C. had established in London. Dr. R. A. O'BRIEN was of the opinion that no scheme for the future of the pathological services need look further than the L.C.C. group system for a plan on which to build. Dr. E. C. BENN (Seacroft Hospital, Leeds) agreed with previous speakers that hospital regionalization was inevitable. He pointed out that each part of the country had its own special problems which required individual solution, and he thought one of the major obstacles to be overcome was local prejudice. Full pathological service should be available to every hospital, but small units attached to small hospitals were as a general rule to be avoided in the interests of economy.

The Sector System as a Basis

Dr. A. G. TROUP (Willesden) endorsed the opinion that the admission of ordinary medical and surgical cases to isolation hospitals was quite a safe procedure from the cross-infection point of view, and gave his experience in this direction in the Willesden Isolation Hospital. Fever hospitals must be considered in any scheme in order that all available beds could be utilized for the maximum benefit of the community. He thought that in the London area the sector system might form the basis on which to found the post-war scheme. He supported the principle of enlarging the better and more modern fever hospitals, and either using for a different purpose or closing the others. This had been indicated in the Local Government Act of 1929 and the Public Health Act of 1936, but no progress had been made owing to the absence of compulsory powers. Finally, he supported the suggestion for some form of regional pathological service.

Dr. F. GRUNDY (M.O.H., Luton) considered that, as pathological services were so highly specialized, a regional or national organization of some sort was ideal. He preferred to substitute for Dr. McCartney's "mobility of personnel" a flexibility of personnel, as he considered that pathologists should remain

specially prepared cinema film called "Out of the Shadow" was shown.

I agree with Dr. Jamison that much could be done by talks on the wireless, but such talks could not altogether replace the more intimate lecture to a small audience which is followed by questions and answers. It is to be hoped that under the Cancer Act the education of the public concerning cancer by means of such lectures will be carried out on a much larger scale, as in my opinion this is the only way to get rid of the fear which is one of the main obstacles preventing the early diagnosis of the disease.—I am, etc.,

MALCOLM DONALDSON,

London, W.1, Dec. 15. Chairman of the B.E.C.C. Propaganda Committee.

Haemoglobin of Pregnant Women

SIR,—During the years 1937 and 1938 and the first two months of 1939 the haemoglobin of patients on their first attendance at the ante-natal clinic of an L.C.C. hospital in North London was determined by Haldane's method. These tests were done at first by Dr. S. H. G. Robinson and later by Dr. W. W. Kay, who has made an extensive analysis of the results which, it is hoped, will be prepared for publication later. There were 2,005 patients, the average of the figures representing the percentage haemoglobin was 84.7, and 107 patients (5.3% of the total) had less than 70% of normal haemoglobin.

After the beginning of the war determinations of haemoglobin were not made for each ante-natal patient until early in 1941. Drs. H. A. Ash and J. M. Alston have supervised from the middle of April to the middle of December of this year the testing of 814 patients at the time of their first attendance, and the average of the haemoglobin figures was 70.8, which is 13.9 less than the comparative figure for the group before war began, and 319 of these (39%) had less than 70% of normal haemoglobin.

In suggesting that it may be concluded that pregnant women in this part of London are distinctly more deficient in haemoglobin than before the war we draw attention to a number of factors which show, we think, that the two groups of figures are comparable. First, the test was made from freely flowing capillary blood in the pre-war group and in almost 40% of the wartime group; from the remainder of this second group venous blood kept fluid by shaking with crystals of ammonium and potassium oxalate was used; the average percentage figure for the specimens taken from venous blood was 2.5 less than for capillary blood and 1.5 less than for the whole of the wartime series. Secondly, before the war many different standard haemoglobin tubes were used for the series of determinations, and these tubes were, by general experience of them, believed to be satisfactory, but since war began it has been found by many pathologists that newly supplied tubes are often inaccurate. For that reason, by the kind collaboration of Dr. Lucy Wills, Royal Free Hospital, the tube used for the determinations in this year's series was checked with and found equal to a standard authenticated by oxygen-combining power. Thirdly, grouping of the patients by ages showed a distribution which was nearly the same before and since the war, and at any rate it was found in the pre-war series that it was only after the age of 35 years that age alone appeared to be associated with haemoglobin significantly below the average. In the pre-war series 8% of the patients were over 35 years and in the war series 9%. Fourthly, the almoner of the hospital has told me that, although she is unable to make an exact comparison of economic circumstances of the patients in the two groups, she does not think that since the war there have been less favourable financial circumstances than before. Fifthly, the distribution according to stage of pregnancy was sufficiently similar in the two groups.

The average figure for the haemoglobin of patients in 1937 was almost the same as 1937 and 1938 taken together (83.5% and 84.7% respectively), so that the state of haemoglobin deficiency was apparently stable in 1937 and 1938. The decrease found in 1941, therefore, is not the continuation of a progressive decrease which was going on before the war. In 1937 and 1938 anaemia was present, as shown by the average haemoglobin value of 84.7% and by the fact that almost exactly two-thirds of the patients for whom the red corpuscles

were counted had a colour index below 0.94. An analysis of colour indices has not been made in 1941, but from the fall of the average haemoglobin value to 70.8% the anaemia is obviously intensified. The conclusion which we think may be drawn is that during this year food taken by pregnant women in this part of London has been inadequate in iron.

We thank the medical officers and members of the nursing staff of the hospital for assistance; and for care and enthusiasm in technical work during this year we are indebted to Mr. R. Rodnight.—We are, etc.,

Haemoglobinometry

SIR,—In their letters Dr. Robert Campbell (November 22, p. 747) and Dr. A. J. E. Mills (December 6, p. 823) point out difficulties in determining the amount of haemoglobin present in blood. It needs to be emphasized that the usual manner of expressing the haemoglobin value is as a percentage of an arbitrary normal, which varies according to the method employed. The normal value is accepted as 100%, this being convenient for calculating the colour index. In Haldane's method this 100% is equivalent to 13.8 grammes haemoglobin per 100 ml. blood; whereas on the Sahli scale the 100% represents 17.3 grammes haemoglobin, or 124% Haldane.

When employing either method these differences must be taken into account, and each tube used for the dilution of the blood should be carefully examined before use. Most haemoglobin tubes are graduated as grammes Hb%, and also according to the arbitrary percentage of Sahli or Haldane. If these tubes are interchanged it is evident that anxiety as to the accuracy of haemoglobin determinations may arise. It would therefore seem desirable that haemoglobin estimations should be reported on a scientific basis as grammes Hb/100 ml. rather than a percentage of an alleged normal. If the latter be used then the method employed must be stated.

Regarding the use of the Sahli instrument, a wait of ten minutes before matching the colour developed with the standard suffices for clinical use. It may be remarked that provided the same technique is employed each time comparable values will be obtained as to the progress of any case.—I am, etc.,

Miller General Hospital, S.E.10, Dec. 9.

W. SMITH.

Red-cell Suspensions in Anaemia

SIR,—I was interested to read Dr. K. B. Rogers's letter on the above subject (December 6, p. 823).

I have given about forty transfusions of cell concentrate, but I find it very difficult to fix with any precision the haemoglobin rise per volume of concentrate given. This must depend on so many factors, such as blood volume, body weight, and capacity of storage of transfused cells, that even an approximation cannot be reached which will be applicable to all cases.

Perhaps an example of two recent cases will emphasize this. These patients were transfused with blood drawn off on the same day, stored for the same time (two days), and decanted on the same day. Further, the same volume was used, and other factors were strictly comparable. The first case, a thrombocytopenic purpura, had a rise of 1% haemoglobin per 28 c.cm., while the other, a gastro-enterostomy, had a rise of 1% per 35 c.cm. The variation in results will be found with fresh blood transfusion also.

It seems to me that it is impossible to achieve mathematical precision in a matter with so many variables.—I am, etc.,

ARCHD. L. GOODALL, M.B., Ch.B.

Congenital Arteriovenous Anastomosis

SIR,—The interesting case described by Dr. A. G. Watkins (December 13, p. 849)—whether there is a free arteriovenous communication or not—shows some dilatation of the internal saphenous vein and increased length of long bones in the affected leg, and therefore obviously belongs to the somewhat loose group which in 1918 (*Brit. J. Child. Dis.* 15, 13) I described under the heading "Haemangiectatic Hypertrophy of Limbs," including congenital phlebariectasis and so-called "congenital varicose veins." On these last I wrote a further note in 1936 (*Brit. J. Child. Dis.* 33, 102). Since 1918 a considerable number

of cases have been described in England and abroad as examples of "haemangiectatic hypertrophy." The increase of length probably occurs only when there is increased blood supply to the growing skeleton of the limb, and is occasionally imitated in Nature's experimental laboratory when a child's long bone is subjected to chronic active hyperaemia as the result of congenital syphilitic osteitis or some other chronic bone infection. Though continual active hyperaemia is the probable direct exciting cause of the increased length of bones in haemangiectatic hypertrophy, the cause of the congenital (developmental) abnormality in the blood vessels remains almost as unexplained as does the monstrous growth of fingers or toes affected by genuine gigantism.

The occurrence of the temporary discharge of lymph suggests that in addition to the haemangiectatic there is also a lymphangiectatic condition present, and that the limb is destined to become the site of intermittent lymphorrhagia. Wherever there is developmental lymphangiectasis a leakage may occur, which, according to the site, will be manifested by lymphorrhagia on the surface of the body, chylothorax, chylous ascites, chyluria, or chylous discharge from the uterus or elsewhere; the discharge of lymph or chyle in such cases may be only temporary or intermittent.—I am, etc.,

London, W., Dec. 13.

F. PARKES WEBER.

Encopresis in Children

SIR.—I was interested in Dr. Charles Burns's article on encopresis in children (November 29, p. 767).

I am not competent to discuss the psychological aspect of the matter, but would like to point out that there are children who exhibit encopresis because of faecal impaction of the rectum, a condition brought on by long-standing failure to empty the lower bowel satisfactorily. This is comparable to overflow incontinence of the bladder, and can be easily detected by rectal examination. I had several such cases, and found that the only satisfactory method of treatment, and one usually affording permanent relief, is digital removal of the faeces from the rectum.—I am, etc.,

Selly Oak Hospital,
Birmingham, Dec. 10.

A. M. NUSSEY.

Combined Intra-uterine and Extra-uterine Pregnancy

SIR.—Dr. R. B. Leech's interesting case reported in the *Journal* of December 6 (p. 805) reminds me of a case which came under my care while I was on the staff of a mission hospital in Northern Nigeria. My case, although not going on to term like Dr. Leech's, is nevertheless unusual enough, I think, to record.

In October, 1939, I was suddenly called to see a young Fulani woman of about 25 years of age who had been staying on the hospital compound looking after her son, who was receiving treatment for sleeping sickness. She had complained of sudden abdominal pain and then collapsed. On examination the abdomen was extremely tender and showed evidence of free fluid in the peritoneal cavity. There was a history of three months' amenorrhoea, and a diagnosis of ruptured ectopic gestation was made. At operation the peritoneal cavity contained free blood, the sac, situated in the right tube, having ruptured directly into the peritoneal cavity. The condition was dealt with along the usual lines. While performing the operation I particularly noticed that the uterus was enlarged considerably more than one would expect for a three-months pregnancy. All went well until the third day after the operation, when the woman complained of "labour-like" pains, and later in the day miscarried and produced twin males, each foetus being well formed and about the size of a three-months pregnancy. This was the patient's third pregnancy, and she afterwards made an uninterrupted recovery.

A case of triple pregnancy, one of which was extra-uterine and the other two intra-uterine, must surely be a rarity.—I am, etc.,

Pulham Market, Norfolk, Dec. 9.

C. E. LANGLEY.

Nail Lacquer Dermatitis

SIR.—Your annotator (December 13, p. 855) states that "little has been heard in this country of dermatitis due to cosmetic preparations for the nails." During the past few weeks I have seen two cases in which sudden outbreaks of swelling and dermatitis of the eyelids, face, and neck have been associated with a sensitivity to a certain brand of nail polish. Positive patch tests have been obtained, and it is hoped to

obtain from the manufacturers samples of the constituents in order to determine the nature of the causative factor.

One lady had been resident in the country for many months. Having children to attend and housework to do she had not used nail polish except on two separate occasions many weeks apart, when the nails were lacquered the night before a proposed trip to London. On each occasion the patient awakened next morning with an intense rash over the eyelids, face, and neck, and herself volunteered the information that she thought the rash associated with the nail-lacquering technique. There was no rash on the hands.

If the co-operation of the manufacturers can be obtained I hope to make a further communication on this subject at a later date.—I am, etc.,

London, W I, Dec. 13.

GEORGE BRAY.

Rehabilitation of the Injured

SIR.—All interested in the problems of the physically disabled must welcome the schemes initiated by the Ministry of Health and the Ministry of Labour and National Service which are referred to in your leading article of December 6 (p. 812). In doing so, however, it is important to remember that we are still far from a "comprehensive national scheme of rehabilitation."

While the Ministry of Labour's plans for the training and resettlement of the disabled will, or can be made to, apply to all classes of disabled, the rehabilitation schemes inaugurated by the Ministry of Health are at present much narrower in their application. They exclude large sections of the accident-disabled—sufferers from traffic accidents, to mention only one—the disease-crippled (unless associated with war service), and children. For all these people it has become more, not less, difficult to obtain specialized treatment, owing to the wartime limitations on normal hospital services.

Those whose work brings them much into contact with the permanently disabled know what a high proportion might have been cured by treatment at an earlier stage and could still be greatly benefited given facilities which, for them, are not available—tragic evidence of the inadequacy of the orthopaedic services which existed before the war, even for children, and of the distance which must still be travelled before anything like a complete national rehabilitation service is achieved. I suggest that it never can be until the many aspects of this complex problem cease to be dealt with piecemeal by a number of different Departments and are instead co-ordinated under a single authority—a Rehabilitation Board—whose sole criterion would be the fact of disablement rather than its cause or the disabled's category.

Glad as we must be of the present advance, so long overdue, the ultimate objective should not be lost sight of. The nation cannot afford to waste its assets, least of all its man-power. What can be done to avoid this by treatment has long been demonstrated. How far training can be effective is becoming increasingly realized. For the past sixteen months men with a high degree of disablement have been training under the munitions training scheme of the Ministry of Labour, and are proving their capacity to work on equal terms with the able-bodied, even under the exacting conditions prevailing in wartime industry.—I am, etc.,

Exeter, Dec. 10.

GEORGINA BULLER.

Medical Man-power

SIR.—As one of the witnesses before the commission investigating medical man-power, I am able to throw some light on certain points raised in Mr. H. J. McCurich's letter (December 6, p. 826). The witnesses with whom I was associated had all been released from the Services to attend to urgent and essential duties among the civil population. They were thus able to give their evidence freely and, I think, fairly.

Where detachments of separate Services are stationed in close proximity it should obviously be possible for one medical officer to care for the medical needs of soldier, sailor, or airman, providing authority for this step could be obtained from the Departments concerned.

I am entirely in agreement with Mr. McCurich in his view that sanitary N.C.O.s could take over the greater part of the routine inspections in camps. In actual fact this progressive step had already been taken by the D.A.D.H. (M.O.H.) in the area where I was stationed. He usually sent his sanitary

sergeant to make a periodic inspection of barracks, and any further action depended on his report. O.C.s of regiments are extremely keen keeping sanitation up to a high standard, and it was rare to find any serious fault.

In recruiting depots where there are a large number of inoculations there seems no reason why trained nurses, male or female, should not be used under the supervision of a M.O. His suggestion that the office of D.A.D.M.S. should be taken over by lay personnel is a more revolutionary one and not likely to commend itself to the powers that be, but it is undoubtedly feasible. A D.A.D.M.S. is the personal private secretary of the A.D.M.S., and it has always seemed a great waste of a healthy young doctor to make him sit on an office stool wading through indents and answering questions which his chief clerk could do equally well. If it is not possible to introduce laymen or women there is no doubt that women doctors could adequately fill this post in suitable areas.

Junior medical officers in field ambulances might be replaced by officers trained in hygiene and in the treatment of casualties during evacuation to hospital. So much of the work of a field ambulance is similar to that of a routine duty of any company officer, and again it seems a pity that a skilled tradesman should be used for this purpose.

Lest it should be thought that this letter is directed entirely against extravagance in medical man-power in the Forces, it is only fair to say that in the larger cities, if the three main services—namely, public health, hospitals, and general practitioners—pooled their resources there could be a considerable saving of medical man-power, and, what is equally important, the public would not suffer.—I am, etc.,

Birmingham, Dec. 9

R. C. L'E. BURGESS.

The Nation's Teeth

SIR,—Referring to Captain G. E. King-Turner's letter on "The Nation's Dental Services" (December 6, p. 827), I beg to point out that, during this war crisis, an exceptional opportunity presents itself for a National Dental Survey which would confirm and accentuate the views expressed in that letter. There is something radically wrong with the nation's dental services; they are not getting positive results. As factory medical officer to the Ministry of Supply, with over twenty-five years' experience of physical examinations in H.M. Navy, I now examine weekly some 300 to 400 new entries of both sexes, drawn from every section of the community. While taking stock of the teeth in a general way, I have also found time to keep records of between five and six hundred—a comparatively small number to date owing to other duties. But from this summary survey one fact emerges clearly—namely, that, despite the treasure that is being expended yearly on school dental services and on dental research, the standard of the nation's teeth has depreciated considerably during the last twenty-five years.

Among the thousands examined here, five Asiatics presented themselves—four Indians and one Burmese. One of these men had had three teeth missing, the other 29 being perfect and free from blemish, and of the three extracted, one sound tooth had been extracted in error. The contrast between the Asiatic dental standard and our own might be described briefly as follows: The teeth were larger and stronger, apparently more fully developed; the arches were wide, making room for full development; uniformity and white ivory aroused one's wonder and envy. All the surgery staff were invited to inspect and admire the beauty of all five as a contrast to what we have become accustomed to.

In examinations of over 1,000 Indian and 1,000 Chinese labour recruits on the Singapore Base (1923 onwards) 87% of Indians and 67% of Chinese exhibited this standard of complete and perfect teeth, free from defect, every tooth doing its duty. A similar examination of the active service personnel of one of H.M. ships in 1921, representing a highly select and well-cared-for part of the general population, revealed only 2.75% of the standard of perfection, but even these lacked the uniformity and ivory-like whiteness of the Asiatic teeth.

I suggest that the opportunity is at hand, and that a National Dental Survey is one of the urgent needs of the moment in the interests of the nation's health.—I am, etc.,

D. H. C. GIVEN, M.D., D.P.H.,
Surgeon Captain, R.N. (ret.)

Obituary

G. DE BEC TURTLE, M.D., M.R.C.P.

The passing of Godfrey de Bec Turtle removes another well-known medical man from the West End of London. Dr. Turtle was a man of many activities: at the time of his death on December 4 he was president of the Medical Defence Union, the Medical Sickness Assurance Society, and of the Clinical Section of the Royal Society of Medicine. He was also medical superintendent of the Luton and Dunstable Hospital, and it was in this hospital that he died after a very short illness.

He was an energetic and enthusiastic worker, and one who always believed in doing things in the right way no matter how much trouble it caused him. After an early medical education in Durham and King's College Hospital he held several house appointments, and became obstetric registrar and tutor to King's College Hospital. He practised for many years in the Hyde Park area, and was constantly to be seen exercising in the Park before breakfast; he always maintained that riding was the best exercise for a busy man, and he advised it for many of his patients.

It is impossible to cover all Turtle's activities, for they were legion. He was interested in the Post Office in the Paddington district, and was one of their district medical officers. He was an ardent supporter and a past president and treasurer of the Harveian Society of London, and the success of that society and its popularity are in great part due to his influence. He also found time to devote two mornings a week to the Public Dispensary, Drury Lane. He was consulting physician to Brentwood Hospital and to the Margaret Street Hospital for Consumption. He devoted much time and energy to the Royal Society of Medicine and was a most useful councillor, having filled the post of treasurer with distinction. Turtle was at his best at one of the social functions of the society, and was always keen to further the society's interest.

He leaves a widow, a son who is in the Royal Navy, and two daughters who are doing war work.

Medical missionary work in China has suffered a severe loss in the death of Dr. FRANCIS HENRY (ROBIN) MOSSE. The son of the Rev. E. H. Mosse, vicar of St. Paul's, Covent Garden, Dr. Mosse was educated at King's School, Canterbury, and Trinity College, Oxford. He studied medicine at King's College Hospital, and in 1913 qualified M.R.C.S., L.R.C.P. Lond. During the last war he served as temporary captain in the R.A.M.C. in Egypt and Palestine, and was with General Allenby's forces at the capture of Jerusalem. But Dr. Mosse's heart was set on medical missionary work, and in 1920, after taking the M.R.C.P., he sailed for China, under the S.P.G., to take up the post of physician to the Cheloo Christian University, Shantung, North China. There for twenty years Robin Mosse trained young Chinese men and women. "A picked group of the finest students in the world," he called them, and he counted himself "the happiest man in Asia" in being allowed to serve them in the name of Christ. He worked with them in refugee camps, in times of flood and famine, as well as in the lecture halls and wards of Cheloo Hospital. After the Japanese occupation of North China the majority of the 4,000 students at Cheloo trekked west to free China, but the hospital remained and Dr. Mosse stayed with it. Early this year he fell ill with tuberculous trouble, and was sent to the U.S.A. for treatment. He seemed to be making good progress, and his death, which followed an operation, was sudden and unexpected.

The death is announced of Dr. HENRY KING DAWSON, senior practitioner in the Ashted area of Surrey. He was educated for the medical profession at Newcastle-upon-Tyne, and graduated M.B., B.S. of Durham University in 1892, proceeding to the M.D. in 1896. During the South African War he served as a civil surgeon with the Gloucestershire Yeomanry, and later with the 9th Lancers and the Coldstream Guards. He began practice at Ashted in 1902. On the formation of the

Territorial Force Dr. Dawson received a commission in the R.A.M.C.(T.), and on the outbreak of war in 1914 was embodied for service and joined the 6th London Field Ambulance, of which he was later given command with the rank of lieutenant-colonel. For his services in France he was thrice mentioned in despatches and awarded the D.S.O. Returning to practice at Ashted he took part in many local activities, and during the present war was appointed medical officer in charge of the local mobile unit. He was on terms of friendship with all his colleagues, and until the passing of the National Insurance Act had been a staunch member of the B.M.A.

The Services

HONORARY PHYSICIAN TO THE KING

Colonel R. Sweet, D.S.O., I.M.S., has been appointed Honorary Physician to the King in succession to Major-General (local Lieut.-General) W. H. Hamilton, C.B., C.I.E., C.B.E., D.S.O., late I.M.S., who has retired.

ARMY AWARD

The Commander-in-Chief, Middle East, General Sir Claude Auchinleck, has, by the authority of the King, approved the immediate award of the Military Cross to Captain John Bissill Haycock, R.A.M.C., for gallantry in action during recent operations in the Western Desert.

CASUALTIES IN THE MEDICAL SERVICES

INDIAN MEDICAL SERVICE

In an India Office Casualty List published on December 11 Colonel EDWARD GALWEY KENNEDY, I.M.S., is recorded as having died. He was educated at Queen's College, Cork, and graduated M.B., B.Ch., B.A.O., of the Royal University of Ireland in 1909. In the following year he entered the I.M.S. as lieutenant, became captain in 1913, major in 1922, and lieutenant-colonel in 1930. In 1937 he was promoted to colonel, and in the same year was appointed Deputy Director-General of the I.M.S. He had been a member of the British Medical Association since 1915.

Captain S. S. Apte and Captain Bazley Rabbi are included as "Died" in an India Office Casualty List published on December 11.

INDIAN MEDICAL DEPARTMENT

Captain R. H. F. Parkinson, D.C.M., is included as "Died" in an India Office Casualty List published on December 11.

Wounded

Assistant Surgeon K. C. Clarke.

POLISH SCHOOL OF MEDICINE IN EDINBURGH

M.B., Ch.B.—W. K. Gatuszka, Jadwiga Mickiewicz, S. Schta, F. Solich.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At an ordinary meeting of the Council of the Royal College of Surgeons of England, held on December 11, with Sir Alfred Webb-Johnson, President, in the chair, Mr. Seymour Barling was re-appointed representative of the College on the Court of Governors of Birmingham University, and Mr. L. E. C. Norbury was re-appointed representative on the Central Council for District Nursing in London.

A Final Examination for the Fellowship will begin on Thursday, February 5, 1942.

Diplomas

Diplomas of Fellowship were granted to the following candidates:

E. O. Harris, H. E. Blake, P. M. G. Russell, V. A. J. Swain, T. L. S. Baynes, B. G. A. Lilwall, E. W. O. Adkins, G. A. Fairlie-Clarke, A. R. Leask, S. I. Green, H. J. Richards, J. Moroney, G. M. Müller, A. G. Apley, J. B. Kimmonth, D. A. J. Ebrill, H. E. Hobbs, W. H. Weston, E. E. T. Taylor, L. H. Aitken, H. B. Boctor, C. H. Cullen, S. Eisenhammer, J. D. Gray, C. G. D. Halstead, J. N. Nish, C. M. Ley, W. Parke, J. J. Richmond, W. E. Springford, N. Waddle.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Physicians of London, to the following candidates:

J. B. Adams, J. H. Crawford, H. de L. N. Davis, D. C. Devitt, R. R. Dickson, J. K. A. Dorman, H. Edwards, H. R. W. Franklin, Ysobel M. Garland, E. F. Gleadow, T. C. Gray, P. S. A. Heyworth, W. Kupfermann, C. B. Lewis, A. M. McKinlay, J. V. Mitchell, L. G. Morrison, G. B. Oliver, J. Patterson, G. Quayle, G. M. Rose, Enid B. Roulston, R. D. Scott, R. P. W. Shackleton, A. A. Shein, Janet Todd, E. C. Whitehall-Cooke, Joyce Worthington, A. M. Young.

Medical Notes in Parliament

National Service Bill

On the second reading of the National Service Bill it was stated for the Government that one woman doctor would be present at the medical examination of women. It was also stated that no woman would be taken from, among other services, full-time Civil Defence work, nursing, and domestic work in hospitals, and teachers would not be disturbed.

During discussion on December 10, in Committee on the National Service Bill, of an amendment proposing not to compel women to undertake service with the Armed Forces, Mr. HENDERSON STEWART said the conditions in A.T.S. camps were bad and also the physical conditions of the girls in many cases. Mr. BEVIN replied that the physical conditions were capable of improvement. With the Service Ministers he was trying to arrive at a proper standard such as they had on the munitions side. The Cabinet agreed that as Minister of Labour he should create hostels near the camps. His Department had received allegations concerning one camp, but an independent investigation showed there was not a single case of venereal disease there. The proposed amendment was negatived.

Subsequently Major HADEN GUEST asked what provision Mr. Bevin would make for detailed hygienic and medical supervision in the new factories which he was providing. No machinery existed, and there was a shortage of medical manpower. Mr. MARTIN asked what measures the Minister intended to take to look after the health of the people who were called up. If women who were constricted became unfit, could they leave their employment on a medical certificate of their own doctor, or would they have to get a certificate from some medical board? Mr. BEVIN said that he could not deal with the nationalization of the medical services under this Bill. The Services were being constantly expanded on the health side, and he had made provision for compulsory medical service in industry. That innovation had expanded and now included nursing.

The clause imposing compulsory service for women was carried by 223 to 0.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a Congregation on December 6 the following medical and surgical degrees were conferred by proxy:

M.D.—T. D. Day.

M.B., B.Chir.—R. E. M. Pilcher, R. E. W. B. Comerford.

UNIVERSITY OF EDINBURGH

At a graduation ceremony on December 12 the following degrees and diplomas were conferred:

M.D.—Fanny B. Chisholm (*née* Mackintosh), C. A. Gleadhill, A. M. Macdonald, Lieutenant, R.A.M.C., J. H. Patterson, Captain, R.A.M.C., J. A. J. Rhodes.

M.B., Ch.B.—I. R. W. Alexander, R. F. Antonio, B. A. Bembidge, G. D. Bonner, W. Boyd, A. K. Brown, L. F. Brown, W. J. J. Bryden, Rosemary E. Buchan, W. Campbell, J. M'D. Corston, J. Devine, N. G. Douglas, N. K. Farley, W. D. Frew, E. R. L. Gregson, C. J. C. Hinrichs, Jean Leith, Anne W. Macdonald, D. Malcolm, A. M. Plant, D. Pottinger, S. I. Pugh, Anne R. M'C. Ross (*née* Sellar), Margaret C. Tate, H. D. Thompson, D. R. Tipping, F. F. Viedge, A. L. Wallis, J. A. Watt, D. B. Wiseman.

DIPLOMA IN PUBLIC HEALTH.—J. A. S. Quata, T. M. Small, Helena S. L. Taylor (*née* Lauder-Thomson).

DIPLOMA IN MEDICAL RADIOLOGY.—R. A. M'Kail.

D.Sc.—In the Department of Pure Science: †C. E. van Rooyen, M.D., Major, R.A.M.C.

* Awarded gold medal for thesis. † In absentia.

The debate was resumed on December 11. On the clause extending the age of men's military service to 50 Mr. MAXTON moved to reduce the upper age to 45. He said there would be a higher rate of sickness, of breakdown, and of discharge in these grades, and either a huge bill to pay through the Ministry of Pensions or a widespread grievance through the country if these men were told their illnesses were those they might have got in civil life and were not attributable to or aggravated by war service. Sir WALTER GREGG said the Government could not accept this amendment. All these men would go through medical examinations, and their duties would depend on their medical grades. Mr. MAXTON'S amendment was withdrawn.

Sir HERBERT WILLIAMS moved an amendment to the clause dealing with persons sentenced for failure to attend medical examination. He proposed that where a person supplied a certificate of permanent ill-health and the attendance at the prescribed place would be detrimental to his health, the medical examination should take place at his home. He suggested that in such cases the man's doctor should send a certificate. Mr. BEVIN said he could not accept the amendment. At present if a person supplied a medical certificate that he was suffering from ill-health and that attendance for medical examination at the prescribed place would be detrimental to his health, that certificate was put before the chairman of the medical board, who might direct that the person should not be summoned to attend unless and until he was fit to go. As the medical board consisted of medical men the Ministry took their advice and acted on it. That was a reasonable precaution against injustice.

The amendment was withdrawn. The Committee stage was completed and the Bill was read a third time.

Having passed through all its stages in the House of Lords, the Bill received the Royal Assent on December 18.

Provision of Wartime Nurseries

On December 9 in the House of Lords Lord NATHAN called attention to the importance of providing an adequate number of wartime nurseries, especially in view of the large number of married women who would be directed into industry. He said that these nurseries must be provided not in hundreds but in thousands. He believed that 200,000 children at least would have to be provided for in such nurseries after every other resource had been exhausted. The Government's own figure for the average number of children in wartime nurseries was forty, which meant that 5,000 nurseries would have to be provided, as against the 500 now contemplated. There would have to be accommodation for the whole twenty-four hours for children whose mothers would work at night.

Lord SNELL said it was impossible to estimate the extent to which women's labour would be drawn upon, but the urgency appeared to be in those key industrial districts which might call for quite rapid development, and that included all the services for child welfare. The Government would have first to observe the rate of intake into industry and then try to provide for nurseries in sufficient numbers in accordance with that intake. It would be unwise to fix in advance any number, which would depend on the rate of intake and the efficacy of any alternative methods that might be tried. Instructions had been given to local authorities designed to ensure adequate preparation for the expected need and to be ready for quick development. The three Departments concerned—the Ministry of Health, the Ministry of Labour, and the Board of Education—were collaborating closely with a view to adequate treatment of this difficult and urgent subject, as were maternity and child welfare authorities and local education authorities.

At the end of November 194 nurseries were in operation, and 209 were approved but not yet in full operation, providing for something over 15,000 children. There were in active preparation a further 264, and the Government felt, with their present knowledge of the need, that this programme was, on the whole, a fairly satisfactory one. Of 125 nurseries approved in November, 33 were allocated to the Midland area based on Birmingham, 20 to the industrial districts of Lancashire, and 17 to the outer districts of London. A suitable staff must include a number of trained nurses, supported by a large number of girls and women for general purposes, and a scheme of train-

ing for such supplementary labour had been worked out. Special arrangements had been made to meet the need for equipment. A list of articles had been prepared, and orders for them had already been placed.

Leprosy in British West Indies

Mr. GEORGE HALL furnished Dr. Morgan on December 10 with the following table setting out the incidence of leprosy in the British West Indies:

Colony	New Cases	Total Cases	Population
Bahamas	1940 3	17	70,332
Barbados	1939 5	63	193,082
Jamaica	1939 Not stated	249	1,193,465
Turks and Caicos	1938 2	5	3,300
Antigua	1940 Not stated	6	36,073
St. Kitts	1939 3	39	37,994
Montserrat	1939 Not stated	Not stated	13,541
Virgin Islands	1940 Not stated	Not stated	6,135
Trinidad and Tobago	1939 77	377	473,455
St. Lucia	1939 5	29	69,737
St. Vincent	1940 Nil	18	61,421
Grenada	1939 Nil	12	90,085
Dominica	1940 3	17	52,738
Bermuda	— Nil	Nil	30,814
British Guiana	1939 45	563	341,237
British Honduras	— Not stated	Not stated	57,767

Mr. Hall added that Dr. Muir, medical secretary of the British Empire Leprosy Relief Association, was in Trinidad holding a temporary appointment as medical superintendent of the Leper Colony, and proposed during his stay to undertake a leprosy survey in the West Indian area. The matter was receiving the attention of the Comptroller for Development and Welfare in the West Indies, and measures were being taken to deal with this disease in all the Colonies concerned.

Medical Certificates

Answering Mr. Rostron Duckworth on December 10, Mr. ERNEST BROWN said he had been asked by the British Medical Association to consider, in consultation with other Government Departments, whether steps could be taken to reduce the demands made on the medical profession for certificates in connexion with war activities. A conference took place between representatives of the Departments and of the Association, at which the whole matter was explored. The matter was now being considered by the Departments individually with the object of reducing to a minimum the number of purposes for which medical certificates were to be required.

Committee on Nurses' Salaries

Mr. ERNEST BROWN, replying on December 11 to Miss Lloyd George, said the committee on the salaries of nurses had held its first meeting on November 27. He intended that in regard to sanatoria and tuberculosis hospitals the committee's scope should extend to nurses possessing or in training for the certificate of the Tuberculosis Association, and that it should also extend to health visitors. Before the scope was so extended some adjustments in the committee might be necessary; and he was consulting the appropriate associations. Mr. Brown added that he had decided to set up a separate committee to draw up agreed scales of salaries for midwives on a national basis. He was consulting the appropriate associations of employers and workers. Lord Rushcliffe was ready to act as chairman of the committee for midwives as well as that for nurses. Some nurses' and midwives' posts involved the practice of both nursing and midwifery, and Mr. Brown would request the committees to consult together before making recommendations in overlapping matters of that kind. Mr. Brown asked for further notice before answering whether the committee would consider residence, uniform, and superannuation.

Rest and Feeding Centres.—Miss Horsham stated, in reply to a question on December 9, that no general standard had been laid down for the amount of accommodation, including feeding facilities, to be provided in rest centres. This had to depend in each area on a combination of widely varying local conditions, and it had been left to each rest centre authority to decide, in consultation with the Department's Senior Regional Officer, what was necessary for its own area. As a rough guide, however, it had been suggested that rest centre accommodation should be provided in target towns and their suburbs for not less than 3% of the population.

No. 49

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 6.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941					1940 (Corresponding Week)

EPIDEMIOLOGICAL NOTES

Discussion of Table

The feature of the returns for England and Wales during the week under review was the very large decrease in the notification of infectious diseases when compared with the preceding week. The largest decreases were those of scarlet fever 91, whooping-cough 234, measles 183, pneumonia 122, and dysentery 32. An increased incidence was recorded for diphtheria 56, puerperal pyrexia 54, and typhoid 10, these increases being due mainly to isolated and widely distributed cases. The only notable local rise was in Yorkshire, West Riding, where diphtheria was 31 cases in excess of the preceding week, due to the experience of the rural districts. The largest fall in the notifications of pneumonia occurred in Lancashire and Yorkshire, West Riding, where the totals were 38 and 48 below last week's figure. The most obvious deviations in the trend of scarlet fever were those of Lancashire, with 32 cases in defect, and Worcestershire, with 20 cases in excess, of the preceding week. The numbers of cases of measles in Staffordshire, Kent, and Herefordshire were 51, 27, and 39 below the totals of the previous week, but in Surrey, Reigate M.B., and Middlesex, Hendon M.B., there were increases of 37 and 21. The decreased incidence of whooping-cough was largest in Middlesex 52, Staffordshire 27, and Yorkshire, North Riding, 27, but—mainly because of outbreaks in Bognor Regis U.D. and Chichester R.D.—there was an increase of 35 cases in Sussex West.

A general decrease in the notifications of infectious diseases was also recorded in Scotland, although there was a relatively large increase, 19 cases, for dysentery.

The 75 cases of measles reported in Eire were an increase of 48 on the total of the previous week. Almost 90% of the cases were reported from two areas—Dublin 35 cases (an increase of 18) and Ballinasloe U.D., Co. Galway, 29 cases.

Dysentery

165 cases, a decrease of 32, were reported in England and Wales. Fresh outbreaks occurred in Nottinghamshire, East Retford R.D., 38 cases, and in Denbighshire, Denbigh M.B., 10 cases. Most of the remaining cases were recorded in Nottingham 38, Surrey 22, Lancashire 20, and Northumberland 10.

The chief centres of infection in Scotland were Renfrew County 11, Aberdeen County 15, and the burghs of Edinburgh 10 and Glasgow 15.

Quarterly Return of the Registrar-General for Scotland

The return for the September quarter of 1941 shows that on the whole Scotland enjoyed favourable health during this period. The civilian death rate was 11.6 per 1,000. The birth rate was 17.5 per 1,000—the highest recorded for any third quarter since 1932. Stillbirths registered during the quarter were equivalent to a rate of 37 per 1,000 total births and was the lowest recorded figure in Scotland for any quarter since registration began in 1939. The infant mortality rate of 63 per 1,000 live births was the highest rate since the third quarter of 1936, and was 6 higher than the rate for the corresponding quarter of 1940 and 4 above the average of the five years 1936-40. Maternal mortality of 4.8 per 1,000 live births was 0.1 below the average for the corresponding quarters of the five preceding years.

The death rate from all forms of tuberculosis was 73, and from respiratory tuberculosis 52 per 100,000. Compared with the average of the five preceding years these rates showed increases of 10 and 6 respectively.

254 deaths were attributed to the principal epidemic diseases; this total was 163 fewer than in the third quarter of 1940. The chief causes of death were diphtheria 88, whooping-cough 83, and cerebrospinal fever 38.

Quarterly Return of the Registrar-General for Northern Ireland

The births registered during the third quarter of 1941 represented a rate of 22.0 per 1,000, this rate being 2.5 above the rate for the September quarter of 1940 and 2.0 above the average of the corresponding quarters of the five years 1936-40.

The death rate of 11.6 per 1,000 was the same as the rate for the third quarter of 1940 and was 0.2 above the average for the five preceding third quarters. Infant mortality was 66 per 1,000 births registered, compared with a rate of 76 for the corresponding quarter of the previous year and an average of 61 for the corresponding quarters of the five preceding years.

Twenty-eight deaths were recorded from whooping-cough—3 above the five-year average for the third quarters, and the 30 deaths from diphtheria were 10 above the average. Deaths from pulmonary tuberculosis numbered 235, compared with an average of 197 for the five preceding third quarters.

Medical News

An open conference on the general topic of "Science and the War Effort" has been arranged by the Association of Scientific Workers and will be held in the Caxton Hall, Westminster, S.W., on Saturday and Sunday, January 10 and 11, 1942. The subjects to be discussed include university training of scientists and training of technical personnel; building, housing, and A.R.P.; food and agriculture; application of scientific knowledge to problems of industrial production and to Services problems, including consideration of industrial health and conditions of work. Those who wish to take part should communicate at once with the conference secretaries, Association of Scientific Workers, 30, Bedford Row, W.C.1 (telephone: Chancery 5201).

Recent events in the Far East lend a grim interest to the report of the Director of Medical Services for Hong Kong for 1940. Dr. P. S. Selwyn-Clarke, in his section on the Civilian Medical (Defence) Scheme, writes that considerable time was spent in bringing up to concert-pitch the auxiliary medical services, such as first-aid posts, casualty clearing hospitals, relief hospitals, etc., for which doctors, sisters, nurses, dispensers, dressers, were trained so as to be available in the event of hostilities breaking out locally. One of the major difficulties was the recruiting of auxiliaries for emergency work, and this was accentuated by the shortage of nurses, due among other things to the compulsory evacuation. The St. John Ambulance personnel, about 1,500 in number, for the manning of first-aid posts in emergency, also had intensive training. The health division of the medical department was reorganized during the year, and the health inspectors worked, for the first time in the history of the Colony, under the direct control of health officers instead of under lay authorities.

At the last council meeting of the Queen's Institute of District Nursing, with Sir William Hale-White, M.D., in the chair, it was announced that the British War Relief Society of the U.S.A. had made a grant of £2,000 to help nursing associations in coastal areas which had suffered from air raids. A gift of £1,200 had also been received through the same benevolent agency from Miss Moule, an American nurse, and a group of her friends, who asked that the money might be sent to the Queen's Institute to help the nurses. During the past year £2,981 was received from the National Gardens Scheme.

Dr. Morris Fishbein, Editor of the *Journal of the American Medical Association*, has joined the British American Ambulance Corps' committee in Chicago.

To commemorate the missionary work of Sir Wilfred Grenfell, M.D., F.R.C.S., in Labrador a special 5-cent postage stamp will be issued in the near future by the Post Office Department of Newfoundland.

A department of nutrition has been established at McGill University, Montreal, in charge of Dr. E. W. Crampton, assistant professor of animal nutrition at Macdonald College.

Sir Henry Morris-Jones, M.D., Liberal M.P. for Denbigh, has been appointed chairman of the Welsh Parliamentary Party.

Major Percy Cecil Parker Ingram, M.B., has been appointed a Deputy-Lieutenant for the County of Monmouth.

General Smuts has lent his support to a campaign launched by South African friends of the Soviet Union for the provision of medical aid for Russia.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles should communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

QUERIES AND ANSWERS

Test for Urease Activity

Dr. J. F. MURPHY writes: Could any reader give me a simple and reliable test for urease activity in blood-urea estimation?

Immunization against Diphtheria

Dr. G. BAYNTON FORGE (Handley, Salisbury) writes: The articles on combined passive and active immunization against diphtheria (November 22, p. 717, and November 29, p. 759) are interesting. I wish to know if the injection of antitoxic serum with the toxoid will prevent the production of diphtheria carriers as will toxoid alone. Is six weeks' isolation for carriers sufficient? It works in closed communities, but what if these cases mixed with the unimmunized population? I have known diphtheria carriers to convey fatal diphtheria at the expiration of twelve months. In France I treated a Belgian soldier who was well into his second year as a carrier, verified by guinea-pig tests, and I left him still a carrier, but I read in the *Journal* some five years later that such cases could be quickly cured by an autogenous vaccine. The 50% increase in notifications of diphtheria in Wales in the past three months and the decline of 50% in the south-western counties for the corresponding period require explanation of the dissimilar effects of immunization. There may be other outside causes which are disregarded. A leading authority in the North considers defective drains to have no effect in spreading diphtheria; others in the South consider festering house refuse to be quite above suspicion as productive of diphtheria. I disagree. I have met many cases which could only be attributed to these two causes.

Income Tax

Partnership Liability

"Y.Z." was in partnership with "X." who left the practice and has not accounted for his share of the tax due for the last year of his partnership. He is abroad, and "Y.Z." is informed that he is liable for the whole tax.

* In strict law this is apparently correct, as the assessment is presumably made on the firm and the partners are jointly and severally liable. In view of the hardship, however, arising in the circumstances mentioned by "Y.Z." we doubt whether the authorities would proceed to extreme measures, and advise "Y.Z." to put the facts before the Board of Inland Revenue and ask them to leave the matter in abeyance until "X." returns from service in the R.A.M.C. abroad and can be sued for his share.

LETTERS, NOTES, ETC.

Status of the Ship Surgeon

Dr. A. GARDNER writes: It has been pointed out to me by a colleague that my letter on the above subject (November 3, p. 671) is liable to be interpreted in a way that was not intended. If so, this is due to the fact that the letter as originally written was meant to cover points mentioned by two other correspondents on the subject. I should like to make it clear that, apart from the first three paragraphs, in which I am in agreement with Dr. James Prendergast, my letter is concerned with service at sea in normal times.

Over 30 members attended the annual general meeting of the Medical Golling Society at the Langham Hotel, W., with Mr. Harold Chapple in the chair. The motion that the society should carry on as usual was carried with acclamation, though it was agreed to postpone competitions for the present.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 5 1941

Correspondence

Medicine and Finance after the War

SIR,—It is significant that of the eight letters in the *Supplement* of June 14 no fewer than seven—all important and well informed—deal with subjects which are engaging our attention, not because the subjects themselves present any difficulties, but because they are matters on which the "dead hand of finance" has cast its blight. Note the titles—"Increase in Private Fees," "Increased Health Insurance Benefits," "State Medical Service," "Free Choice of Doctors."

Every one of the writers, whether he knows it or not, is anxious to obtain (1) relief from economic distress or worry; (2) a medical service unhampered by economic limitations. To attempt to obtain this happy state thousands of medical men all over the country have thought, spoken, argued, written, formed committees, framed resolutions, and devised plans. They have spent an enormous amount of time, and mental and physical energy, in the past months "trying to arrive at a solution." And always they have come up against opposition of one sort and another which has been called "personal ambition," "Fascism," "an inopportune time," or some equally high-sounding phrase. A few moments' honest thought will reveal that each of these objections or barriers is merely a cloak for lack of money. The scheme is impracticable because we "cannot afford it." Mr. So-and-So opposes it because he fears "it will affect his income." A medical analogy is that of sciatica or sciatic neuritis. "Sciatica" is a descriptive term, a symptom. There is always a cause for which we have to seek. The causes are legion. The multifarious symptoms of "lack of money," on the other hand, are due to one and only one cause—*lack of money*. Once this lack is righted all schemes can be put into action at once and fully.

The lack of money is an artificial thing, as we all know now. Prior to this "war" the country could not find two or three million pounds to put agriculture right. Now we can conjure up fourteen millions a day without any difficulty. So absurd is the situation that people have stopped saying, "Where is the money coming from?" They know. All the financial papers have explained over and over again that the Bank of England creates it. Why, at the start of London's War Weapons Week it was bluntly stated that little if any of the money subscribed it would be saved money. It would be money created for the purpose. The financial authorities have even gone so far as to say we are not asked to save money because the country needs it—only because they want us to stop spending.

The lack of money is selective whether in war or in peace. In wartime ordinary consumption must be cut, so it is right that the people—the consumers—should have less. But in peacetime lack of purchasing power by the consumer is a sheer anachronism. If they cannot purchase why bother to produce for purchase? It is lack of money by the consumer which is the flaw in the orthodox (namely, old-fashioned) financial system. It is this lack which is hindering medical development—which makes the time-wasting and energy-wasting medical planning schemes necessary.

Away with all this waste. Let us get back to first principles. Let us demand a sensible financial system. Let us devote all our energies to this and our problems can be solved at once. It will be said—and justly—that the selfishness of some people may jeopardize the schemes even then. Quite true. But the selfishness of a few people who control the Bank of England is sabotaging all schemes at present, including the war effort, as we see in "Treasury's Dead Hand is slowing down War Effort" in a national daily of June 3. It was

said by Edward Hulton in *Picture Post*: "Most of us accept that 'money' is but counters. . . . It is about time we began from the Treasury downwards to act on that belief."—I am, etc.,

Manchester, June 17.

W. SAYLE CREER.

Medicine To-day and To-morrow

SIR,—May I offer the following reflections on recent correspondence in the *Supplement*.

After ten years' struggle against the limitations and irritations of suburban general practice as it is conducted to-day I, like most of my colleagues and contemporaries, am all too often conscious of a sense of dissatisfaction and frustration. Many of us feel more and more that we are not getting a fair deal financially, and that much of our time, training, and skill is wasted; in fact there is little to encourage a young practitioner to live up to the high ideals with which he first embarks on his profession.

A properly organized national medical service would do a great deal towards the building of a very much better and healthier nation when this nightmare of war is over, but a State Medical Service run by civil servants will, if our present experience is any guide, lead only to still more widespread dissatisfaction among the profession. No group of men can be expected to give of their best while they labour under a sense of grievance and feel that they are unfairly treated, and the end-result would be a steady decline in our standards, and we should in time cease to be a "learned profession"; a cynic might well suggest that we are already on that downward path!

Though we can none of us hope to keep up our pre-war standards of living in such days as these, yet while aiming at a higher level of medical service so that the best men will be attracted to practise medicine and will be encouraged to give of their best, the conditions under which we serve must be satisfactory—and that must include a satisfactory economic standard. For this reason most of us will disagree with those few correspondents (is it just coincidence that they are apparently all from "reception areas" and are so perhaps not solely dependent on current professional earnings?) who deprecate any attempt to secure a *net* income for the general practitioner. Actually our present *net* fees are less than pre-war fees if allowance is made for increased practice expenses, and even the recent increase in gross private fees does not balance the account.

As for the proposed extension of insurance benefit to a large group of "black-coated workers," if these patients, who at present pay fees which average four or five times the current capitation fee, are to be accepted at that same rate, we shall in effect be subsidizing out of our own pockets patients who are often very exacting in their demands upon us. If our representatives agree to these proposals they will be guilty of a gross betrayal of our interests, and will forfeit all claim to the confidence of general practitioners.

What we all long for is a well-organized health service in which we can all give of our best for the good of the nation's future health, and in return we ask for fair conditions and fair treatment. At present we get neither of these, but is it too much to hope for better things in the post-war future?—I am, etc.,

Coventry, June 17.

H. NORMAN GREGG.

MEDICAL PERSONNEL (PRIORITY) COMMITTEE

The Secretary of the Central Medical War Committee, Dr. G. C. Anderson, has been invited by the Minister of Health to attend the meetings of the Medical Personnel (Priority) Committee, the chairman of which is Mr. Geoffrey Shakespeare, M.P., in order that the committee may have the benefit of his advice and experience in the course of its discussions.

DEATH

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 12 1941

ANALYSIS OF 2,500 PANEL PATIENTS EXAMINED UNDER THE REGIONAL MEDICAL SERVICE IN 1937-8

BY

J. F. DOW, M.D.

*Late Part-time Medical Officer, Regional Medical Service;
Staff Medical Officer, Westmorland County Council*

Up to the outbreak of war the Regional Medical Service reviewed a large number of panel patients, the object of this examination being: (1) to report on the progress or otherwise of the patient; (2) to confirm the diagnosis and perhaps assist the panel practitioner by some hint of treatment; and (3) to remove cases of malingering from the benefit list. It must be stressed that these cases were almost entirely referred by the approved society, and their selection depended on: (1) The certified cause of incapacity. A society was far more likely to refer a person if the certified cause of incapacity was stated to be a trivial one—such as dyspepsia or catarrh—than if it was a more serious ailment. (2) On the information the society had obtained from their sick visitor about the member's recovery or unwillingness for some reason to "sign off" the funds. This method of examination, while providing a check on the benefit expended, was also of value in limiting unnecessary absence from work, which may be a cause of some anxiety at the present time. It is also obvious that cases so selected cannot be a fair sample of the sickness in the district.

During the year 1937-8 statistics were kept of 2,500 consecutive cases examined at Regional Medical Centres. The area from which the patients were drawn was a northern one in which heavy engineering, industrial, and rural workers made up the majority of those examined. In all 757 men and 1,743 women were examined in the following age groups:

Age Group	Men	Women
16-25	95	474
26-35	106	451
36-45	121	337
46-55	193	243
56-65	240	233

It may be noted that while only 42% of the men were under the age of 45, no less than 72% of the women came in this category; this would seem to be of special importance in view of the large amount of female labour now employed. The occupations were as follows:

Men	Women
Labourers 276	Textile 830
Engineering 96	Domestic 563
Transport 87	Shop assistants 146
Textile 84	Clerks, typists 43
Shop assistants 35	Laundry workers 39
Ironers, etc. 33	Confectioners 32
Miners 32	Nurses 13
Clerks 31	Various 62
Various 79	

Disabilities causing Absence from Work

One of the difficulties of analysing cases of sickness in general practice is that the signs and symptoms in a large proportion are so ill defined that it is very difficult to classify them. Therefore, in the following list of disabilities the diagnosis is that which seems to me most appropriate after careful examination, and it must be admitted that another practitioner might pigeonhole them differently. Thus the class labelled "Various" includes a number of cases which might be

labelled "Debility," and which could be due to nervous depression, septic teeth, etc. The disabilities which were identified as the cause of absence from work were as follows:

Disabilities	Men		Women	
	Number	Percentage	Number	Percentage
1. Anaemia	10	1.2	226	13.0
2. Appendicitis	11	1.4	37	2.1
3. General debility	12	1.5	92	5.1
4. D.A.H.	45	5.9	42	2.4
5. Diabetes	14	1.3	13	1.7
6. Eye diseases	12	1.5	25	1.4
7. Digestive disturbance (non-malignant)	75	9.9	26	1.4
8. Graves's disease	—	—	17	1.1
9. Gynaecological conditions	—	—	43	2.7
10. Hernia	13	2.3	7	0.3
11. Hyperpiesis	37	4.3	23	4.4
12. Injuries	26	4.3	37	2.1
13. Neurasthenia	63	8.3	146	7.7
14. Chest diseases (non-tuberculous)	87	10.1	89	5.1
15. Nephritis	34	4.5	33	2.2
16. Organic nervous disease	25	3.4	31	1.7
17. Rheumatism, arthritis, etc.	85	10.1	131	7.5
18. Tuberculosis	32	4.2	76	4.3
19. Valvular disease of the heart	26	3.4	73	4.3
20. Varicose veins	3	0.4	33	1.3
21. Pregnancy	—	—	133	7.6
22. Malingering	20	2.6	115	6.6
23. Various	111	17.9	225	12.4
	757	100	1,743	100

Notes on Diseases

Anaemia.—It is at once obvious that this remains primarily a disease of women; no case was counted as one of anaemia where the haemoglobin was over 65%. Of the women with anaemia, 90% were under the age of 45 and 40% under 25; they were found specially among textile and domestic workers, and the condition was often the result of parturition. It is a curious fact that these cases were rarely accompanied by the textbook complication of gastric and duodenal ulcers, as might be expected.

Appendicitis.—There were more cases among women than among men, due, possibly, to the more common occurrence of constipation owing to sedentary work. Statistics were taken on the last 1,500 cases examined, and these showed that twenty-nine men (6%) and 117 women (11.5%) had had appendicectomy.

D.A.H.—The percentage of men suffering from this condition was twice that of women, due to more strenuous work.

Digestive Disturbances (Non-malignant).—These comprised gastric and duodenal ulcers, gastritis, etc., and they occurred seven times more often among men than among women, and were one of the three main causes of disability. The cases were distributed fairly equally among the occupations, but transport workers and labourers were especially affected. Hasty meals, heavy work, and the position of a driver in a transport vehicle can all be considered as contributing causes.

Chest Diseases (Non-tuberculous).—These again were twice as common among men as among women, and the same applied to nephritis and rheumatism. Exposure to weather will account for the preponderance of these three diseases.

Malingering.—The figures here applied to cases of genuine malingering and not to patients who had recovered from illnesses. The malingers had apparently never had any disability sufficient to prevent their working. The percentage among women was nearly three times that among men, and of the

115 women eighty-one were under the age of 35. A certain amount of this was found in persons who were in seasonal employment, but there were a considerable number who seemed to have ceased work deliberately and gone on to the panel for a holiday. These figures are undoubtedly very conservative, and, as stated, make no allowance for persons who had been ill and were reluctant to return to work.

Conclusions

It is, of course, of the utmost importance that in work for the national effort as few hours as possible should be lost. In the case of men it is clear that there is much preventable illness which is due to exposure or bad and hasty feeding. The last-named could be remedied by well-organized works canteens and the first by attention to exposure. Neurasthenia was also slightly more prevalent among men than women, and this was often due to long hours, especially in transport drivers.

As regards women, 25% of the disabilities are due to anaemia, neurasthenia, and malingering. Anaemia is certainly preventable by healthy supervision, but malingering presents a problem which may cause a serious loss of time now that women are more universally employed. With the cessation of the Regional Medical Service there can be little control, as the medical officers of industrial firms will find it very difficult to deal with such cases.

Correspondence

State Medical Service

SIR.—I have been following with great interest the correspondence in your columns for and against a State Medical Service. It is a question which has occupied my thoughts ever since I was first qualified. One or two points which I do not recollect as having been put forward as yet bear on the financial aspect from both the patient's point of view and the doctor's.

In order to provide a comprehensive service for everyone—and nothing else is worthy of consideration—much costly equipment will be required and proper facilities for using it. It is pertinent to ask where is all the capital coming from to provide this if not from the public as a corporate body—that is, the State? The finding of capital has been a bugbear to many men on starting in practice: as things are likely to be when the war is over, it is mighty difficult to see where the men with £4,000 or £5,000 available for the purchase of a practice are going to be found.

From the patient's point of view, he simply will not have the money to pay all the various specialists who may be required for the thorough investigation of his case. It is idle to pretend that any one man can now put himself forward as a proficient adviser in all illnesses and disabilities. If the patient is going to have access to proper treatment in proper surroundings whenever he is ill I, personally, cannot see how such a service can be provided except by the State.

As for free choice of doctor, I have always suspected that this slogan was raised as a special war cry by the opponents of change, the *laudatores temporis acti*. Our fathers and our grandfathers, with their impressive raiment and heavy gold watch chains, were probably in their time sufficient of a host in themselves. With the advance of medical and allied science to what it is at the present day I say, emphatically and challenging contradiction, that we of this year of grace are not: we should only be allowed to hunt in teams. That brings up the letter of Dr. Frewen Moor (*Supplement*, June 21, p. 84). May I speak a parable?

In a certain town where the doctors numbered less than twenty a scheme for the temporary amalgamation of all the practices on almost exactly the same lines as Dr. Frewen Moor suggests was considered shortly after the present war broke out. The idea was to safeguard the interests of the men who left the town on Service, to prevent the "pinching" of patients, and to effect economies in the buying of drugs, the employment of dispensers, and the closing of redundant surgeries. All very worthy objects. Meetings were held where all were invited to express their views and make suggestions. At the outset one single-minded practitioner signified his intention of remaining outside the scheme; the remainder were all in favour of it, in praising the manifold advantages the scheme presented. Accounts were written and found correct, a final instrument was drawn up, and all that remained to be

done was the formal witnessing of signatures, when one of the younger men suddenly decided that he would do better financially by staying out, so the whole edifice collapsed—torpedoed without warning. And this no doubt will be the fate of the majority of such schemes until a certain amount of compulsion is used. And by whom can such compulsion be exercised except by public opinion—again the State?

A vested financial interest in disease should surely now be regarded as a relic of barbarism, one of the worst of the legacies left to us by our predecessors. The present chaos in medical practice is due to the triumph of the commercial spirit over the idea of service—that is, the doing of the very best possible in all circumstances for the patient. Men are encouraged to take on ever so much more work than they can possibly do so that X and Y shall not do it: is this in the true interest of the patient? Many of us must have seen chronic invalids who have become so because some kind doctor with a good bedside manner—and a keen eye for the guineas—has encouraged them to be ill and to expect the constant attendance of a doctor. These are hard words, but will any gainsay them? That the very best and keenest work can be done without any commercial urge behind it is being shown every day and has been shown for centuries by the fighting Services and by the whole-time civilian medical services.

It is this spirit of service—the doing of a job well for the sake of the job itself and not from hope of pecuniary reward—which the medical schools ought to cultivate in their students. Commercial medicine is failing—has failed. Is it not time the public were given a chance to see what a profession prompted purely by ideals of service could do? I cannot very well sign my name to this letter for reasons which need no statement, so will sign myself once again

June 24.

IGNOTUS.

SIR.—The discussion upon the subject of a State Medical Service which you have permitted until this date has been full of interest, and especially so to some of us who, between national health insurance and the Highlands and Islands of Scotland Medical Service Fund, are for practical purposes a State service. Our private practice, although not negligible, is very small. So far as I can make out, all are quite comfortable and happy, and there is considerable competition when a vacancy occurs to get among us.

It does not help this discussion to have a man in the position of Dr. Frederick Porter writing (*Supplement*, June 21, p. 84) regarding the service to which the bulk of his colleagues belong that it was "a gross interference with the freedom of the individual, and would in no way benefit the general health of the worker . . . that it would lower the prestige of medical men and the practice of medicine to a commercial undertaking . . . that it lowered the standard of medical practice . . . that free choice of doctor only existed on paper."

I have worked under national health insurance from its beginning in a wide and large rural practice. For several years I have been chairman of both Insurance Committee and Panel Committee in this area, thus holding the confidence of both the lay and the medical side of the system. Unless I am a fool, I should know something about it and the truth or otherwise of the statements made by Dr. Porter. National health insurance has in this area been a great success, and the prestige of the medical men of the county of Ross and Cromarty never higher. We can visit our folk and prescribe for them, no matter what the cost, as much as we feel it our duty to do. We have the satisfaction of knowing that we do not overburden the poor. The insured are much better off than the non-insured. We have not thus to descend, as Dr. Frederick Porter would suggest, to "commercialism." We have not, in this area, ever had one of our colleagues fined for over-prescribing, and neither my Insurance Committee nor Panel Committee would permit such a thing so long as there was not silly extravagance, which there has not so far been. Whatever the opinion of the Department of Health may be, it does not interest us, and our freedom of practice has not only not been restricted but definitely increased. We can carry out the highest traditions of medical practice, and, although we would not grumble at a little more to our capitation grant, well, seeing that half of it would have to be returned in income tax, we are not grumbling very much, and are much better off than in 1911. In this area I think who is to change has to do so on his own. I have lost of late every year, and am still crying, although that they got rid of me before I got rid of them.

CORRESPONDENCE

JULY 12, 1941

I have no difficulty in getting rid of those whom I cannot get on with and who upset me in my work. To succeed in medical practice there must be absolute trust and co-operation between physician and patient. If one cannot have this, then part. I would never attend those between whom and myself there is a barrier, even temperamental. It is not the public who are always to blame; I am often to blame, but the fact remains, and we must separate. I have never seen difficulty on either side.

"State Socialism," as Dr. Porter would have us call it, has never restricted our work in any direction if we, as individuals, are willing to carry out work in any way we fancy and which is for the benefit of the public. I do not think I have seen a Departmental official in my area for years. I have never known a legitimate request to be refused myself or any colleague. If you want anything from the Ministry of Health or the Treasury you must produce hard proved facts. When we produced these two years ago, we got what we wanted. We had the same experience before the Lord Dewar Committee. The returns we have to keep are very simple. We are paid under our capitation grant to keep notes—a fact not realized by many—and it would help us as a profession and as individuals if we kept them better.

I hope we have a State Medical Service, and, however it is planned, it should not be beyond our capacity to work out such a service to our own and to the public's advantage. As it is, to-day we and the public are far better off than before 1911, but both have a long way to go yet to attain perfection. It does not help either of us to write what is not true, to belittle our own progress during these last thirty years, or to talk of "commercialism" when we know that we are all just as keen on cash as the village grocer.—I am, etc.

E K MACKENZIE

Tain, June 22.

SIR,—Dr. Frederick Porter (*Supplement*, June 21, p. 84) says: "For a patient to change his doctor requires so much red tape that patients would refuse to use it, which is the case." Every insurance doctor knows that this is not correct. There is no red tape involved, and patients do transfer freely and sometimes very surprisingly. I may say that I am not one of those in favour of a State Medical Service.—I am, etc.

SEYMOUR W. DAVIES.

Wirral, Cheshire, June 24.

State Medical Service: An Islington Resolution

SIR,—In view of the great interest displayed by the medical profession in (1) a State Medical Service and (2) the composition of the Medical Planning Commission, it may be instructive to give you an account of a meeting of general practitioners, mainly of the Islington area, but at which several doctors from adjoining boroughs were also present. This took place at the Royal Northern Hospital on June 24, and fifty-eight doctors were present though only forty-nine are recorded through an oversight.

A scheme for a State Medical Service was discussed at length, and a plan for putting it into operation was presented to the gathering. A good deal of criticism was expressed of the Planning Commission because general practitioners were not represented on it in proportion to their numbers in the medical profession. The following resolution was passed by 35 votes to 4:

"That this meeting of North London medical men, having discussed the question of a State Medical Service, is in favour of this, considering that it will be, first, in the interest of the public, and, secondly, in the interest of the medical profession. It is resolved that the success or failure of such a scheme depends on the adequate representation of the general practitioners of the country. We therefore demand that the general practitioners should by free election appoint their members to form a majority on a planning board for the institution of a State Medical Service."

A committee was elected to implement the decisions arrived at, and to link up with practitioners in other areas who hold similar views.

We are very interested in the manifesto by the "Younger Half" on Medical Planning Research (*Journal*, June 28, p. 976), in that it shows the great ferment working in the minds of medical men in the country generally.—We are, etc.,

B. HYNES } Hon. Secs.
P. INWALD }

On behalf of the Practitioner Co-ordinating Committee

London, N.19, July 1.

UNEMPLOYMENT INSURANCE AND SALARIED HOSPITAL APPOINTMENTS

In the *Supplement* of November 9, 1940 (p. 40), reference was made to a ruling by the Ministry of Labour that unemployment insurance contributions were payable in respect of medical practitioners holding salaried appointments at voluntary hospitals where the remuneration plus emoluments was at a rate not exceeding in value £420 a year. As a result of further correspondence with the Ministry the Secretary of the British Medical Association has received the following letter dated July 1, 1941:

"I am directed to refer to previous correspondence . . . regarding the position . . . of medical practitioners holding salaried appointments at voluntary hospitals. I am to state that the position has been reviewed and the Department is now of opinion, as advised, that doctors employed by hospitals and institutions are not normally employed under conditions which constitute employment under a contract of service. It is not, therefore, necessary to make special provision for exclusion from unemployment insurance of salaried doctors employed by public or local authorities. Unemployment insurance contributions are not normally payable in respect of doctors employed in any hospitals or institutions, and the opinion expressed in this Department's letter of October 29, 1940, should be regarded as reversed."

PETROL FOR DOCTORS

As a result of the strong representations made by the British Medical Association to the Petroleum Department, the arrangements for supplying petrol to medical practitioners have recently been more satisfactory. Delays have been reduced by the plan of "staggering" the rationing periods, whereby applications from doctors for supplementary allowances receive the undivided attention of the authorities at times other than those fixed for the receipt of applications from the rest of the motoring community. Comparatively few complaints have recently been received at the Head Office of the Association, although the medical liaison officers are still called upon to deal with many cases of difficulty. The Association is in communication with the Petroleum Department and will do its utmost to secure a remedy of any legitimate grievance brought to its notice.

Unfortunately, however, it is necessary to emphasize again the fact that the arrangements cannot work smoothly without the fullest co-operation of the profession. Often it is found that doctors who complain are themselves solely responsible for their difficulties. They have, for example, ignored the instructions about the date of application, or they have failed to give timely warning of their need for an allowance additional to the supplementary ration received, or they have simply demanded allowances which their own mileage figures show to be excessive without making the slightest attempt to explain or justify their claims.

The Association has recently explained to the Petroleum Department that very many doctors—particularly general practitioners in reception areas—are seriously overworked and have no time to use their cars for purely private purposes or to visit their patients except by car. An assurance has been requested and received that there is no intention to withhold from doctors petrol which they need for the discharge of essential services necessarily involving the use of a car.

Protests that doctors generally should be exempted from the "cut" being made in the supplementary allowances appear to be unreasonable. It is realized, however, that, owing to the special circumstances of the times, some doctors cannot appreciably reduce their consumption even during what are normally the slack months of the year. Any doctor who genuinely needs the same allowance as he has obtained during the winter will receive it, but it is fair that he should be asked to provide satisfactory evidence in support of his claim. It should be obvious that the fact that many people are still using petrol for illegitimate purposes does not justify a doctor in expecting to receive a specified amount on demand without showing that it is required for professional use, and it should not be necessary to add that the use of any petrol beyond the basic ration for holiday journeys is both wrong and illegal.

Complaints received show that a recent circular issued by the rationing authorities made the suggestion that doctors may be required to produce a log of all their journeys. Unfortunately this suggestion was made without prior consultation with the Association, which will do everything possible to

MARRIAGE AND DEATHS

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 19 1941

Correspondence

Capital Value of Practices

SIR.—The threat of confiscation of capital values of practices should not be allowed to prejudice medical men against a State Medical Service. Certainly full payment should be made for all practices if a State Medical Service is established. But equally certainly this payment should be made by those who would have paid for the practices but for the establishment of a State service—namely, the medical men themselves.

This manifestly equitable principle could be equitably applied. A doctor having a practice worth £2,000 might get a post in the Service, worth £2,000, or less, in which case he should be credited with the balance, or more, in which case the deficit should be debited in his account in the appropriate State fund. Salaried doctors could be similarly compensated for what they lose and made to pay for what they gain by manipulation of the books of the State fund.

This State fund would doubtless be the doctors' and doctors' dependants' pension fund. Its whole inception could be no more than a vast book-keeping transaction that hardly disturbed public or private finances. Doctors without capital would no doubt prefer to have reasonable deductions made from their salaries instead of having to provide unreasonable profits for agents, banks, and insurance companies.—I am, etc.,

Llanbadach, June 29.

WILLOUGHBY CLARK.

State Medical Service

SIR.—In all the letters as between the advantages of individual practice and a State Medical Service it is assumed that there is no alternative twixt the two. As a general practitioner of approaching thirty years' standing I find myself dissatisfied with competitive practice in that so much useful experience is wasted because it is so difficult to find the necessary time to correlate useful experiences with useful study. Such leisure as the G.P. gets is tired leisure. Also I am dissatisfied because of the impossibility of achieving security of livelihood against accident, sickness, and old age. It is unsatisfactory also because we as G.P.s lack the immediate necessary help that should always be available in our surgeries and also in the inadequate equipment at hand by means of which our work can be effectively expedited. We wither for want of means. And for these reasons most of the really responsible work of the profession has already left us. We have become a sideline from which serious responsibility has already been abstracted.

There is, of course, freedom of choice for patients to choose their own doctor. But freedom of choice implies inefficiency in our ranks. What knowledge does the man in the street possess to entitle him to be the chooser among us? We should be so trained and directed that we are all efficient; the profession should do the choosing, for we have the necessary knowledge to know whom to choose.

We are advised to "stick to our last." This implies that the pursuit of general practice should be a whole-time job, which, in fact, is what competitive practice turns out to be. But work should be for life and not life for work. It is this complete subordination of the personality to the job which turns citizens into robots—timid robots at that—who are afraid to take part in social pursuits for fear of losing patients thereby.

Is there then no alternative as between the pursuit of practice by the individual with all his limitations and a State service

with its possible subordinations? Of course there is. The object of the profession is to render service, and that in the highest degree. To that end we should work together and not pull apart. This is obvious enough, but what does not seem to be sufficiently obvious is that the buying and selling of practice goodwill is the first and most serious stumbling-block to co-operative effort. Can we not first rid ourselves of this evil thing that demands of young medicos already trained and ready for service that they shall pay for the right to work? And what right has any man to sell the affections and loyalty of his patients to another doctor?

First let us cast out this evil; then we shall see clearly how to organize ourselves in such a way as to offer the public a united and efficient service.—I am, etc.,

South Norwood Hill, July 1.

J. C. JONES.

Medical Certificates

SIR.—In all the correspondence that has recently appeared about medical certificates there is one aspect of the question to which little attention has been drawn, but which is becoming a very great nuisance to the general practitioner and especially to the panel doctor. I refer to the demands made by employers for medical certificates. Most firms demand these from any workman who is absent even for the shortest period, and if the disability lasts he has to provide weekly certificates and finally a certificate of fitness. In addition, in cases of workmen's compensation, workpeople are required to provide certificates forward to the insurance companies.

All these are demanded by the employer without offer of payment, and all one can get as a rule is 6d. per certificate from the workman. I understand that the Workmen's Compensation Act specifically states that, where an employer requires a certificate for purposes of compensation, the fee must be paid by the employer. I have repeatedly tried to extract a fee from the employer, but my successes have been very few, and if I refuse to furnish a certificate it is the workman who suffers because he gets no money. Surely it is possible to prevent what is nothing more or less than wholesale exploitation of the profession by employers throughout the country.—I am, etc.,

Wolverhampton, June 23.

W. R. SOMERSET.

Domiciliary Visits of Public Vaccinators in Wartime

SIR.—There is one aspect of a public vaccinator's duties which would seem to call for a wartime modification. For the benefit of those members of the profession who are not familiar with the duties of the public vaccinator, I would mention that a practitioner holding this appointment receives periodically from the local medical officer of health a list of those infants residing within the district who have reached the age of four months, and in respect of whom the M.O.H. has not received either a certificate of successful vaccination or a formal objection to vaccination. It is then the duty of the public vaccinator to visit the homes of these infants, and to offer to vaccinate the children in the prescribed manner.

In my own case I receive each month a list of some seventy to eighty such names, and to the parents of each child is sent a notice of my intention to call on a certain day in order to offer to vaccinate the child. On an average I visit seventeen homes a week to make the prescribed offer of vaccination, covering in the process a daily average of twelve miles. Although the vaccination visits are timed so as to fit in with my ordinary round

E. B. GREGONO, M.B.,
Surgeon Lieut. R.N.V.R.

[illegible]

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 26 1941

INSURANCE CAPITATION FEE MEETING OF INSURANCE ACTS COMMITTEE

A meeting of the Insurance Acts Committee was held on July 10, with Dr. E. A. GREGG in the chair, when the time was almost wholly taken up with the discussion of an amended offer by the Minister of Health concerning the capitation fee and with business in anticipation of the forthcoming Panel Conference, which was fixed for July 31.

The Government Actuary, Mr. G. S. W. Epps, C.B., accompanied by Mr. H. H. George of the Ministry of Health, attended the meeting in order to give the committee information on the financial provisions underlying the new National Health Insurance Bill. A report by the Government Actuary on this subject (Cmd. 6290) had been issued that same morning. Mr. Epps explained that the cost of medical benefit did not depend upon whether the contribution income in a particular year was at a certain level, or was unduly influenced by unemployment. It was not a question of balancing the income and outgo of a particular year, but of arranging an insurance scheme involving a long-term contract—actually from the ages of 16 to 65—with the building up of a reserve in the earlier years of membership which was likely to be expended in the later years. The two problems in the new Bill were the increase of benefits by 3s. and the bringing into insurance of a relatively small number of people (with incomes between £250 and £420). Mr. Epps went on to say that the total provision for fixed charges on the finance of health insurance, which at present is 17s. 6d. per member, will, as from 1942, when the new arrangements obtain, be 20s. For what is known as the medical pool the previous figure of 13s. expended in medical benefit and administration will become 14s. 6d., and the other shilling of the added half-crown will be for the administration of sickness benefit, allowing a margin for contingencies. Last year the sum for administration of sickness benefit, which should have been 4s. 6d., had risen to 4s. 10d., and in view of various charges on the societies—he mentioned in particular the making up of salaries of employees called up for national service, increased remuneration of junior staff, and A.R.P. provision—it seemed likely that next year might see a 9d. addition to the 4s. 6d., leaving with the new allocation of 1s. a small margin.

He gave some figures as to the manner in which the original allocation of 13s. for the medical pool and the new allocation of 14s. 6d. were made up. The 13s. consisted of the following items:

	s.	d.
Practitioners' capitation fee	9	0
Mileage	..	4
Drugs	..	2 11
Insurance Committees' administration	..	6
Central administration	..	3

Last year the actual expenditure on drugs represented 3s. 6d. (the price was now going up owing to the effect of the purchase tax and other causes); Insurance Committees' administration costs were 6½d., and central administration costs 1½d., the reason for this last reduction being the cessation of the regional medical service, which cessation, of course, was only a temporary war-time measure. The total additional expenditure was thus 5½d., which meant a deficit at the end of the year of £300,000. The new allocation of 14s. 6d. was as follows:

	s.	d.
Practitioners' capitation fee	9	6
Mileage	..	4½
Drugs	..	3 7
Administration (local and central)	..	10

This left a margin of a fraction over twopenny. Asked whether if the capitation fee were raised to 9s. 9d. it would make the fund insolvent, Mr. Epps said that it would be a gamble on drugs not costing more than 3s. 7d., and on the saving of a farthing on administration.

The Government Actuary was thanked for his assistance, and in reply said that, of course, he was not concerned with policy but only with calculations.

Minister's Amended Offer

After the Actuary had retired Dr. Anderson reported that following upon the deputation to the Minister on June 30 an offer going rather further than his previous one had been received—namely, an increase of the capitation fee to 9s. 9d. The Minister's undertaking to have a complete review of the adequacy of the capitation fee immediately after the war still remained. It was explained that 5½d. of the additional 9d. was taken as meeting the increased practice expenses, and the remaining 3½d. was added in respect of the new group of insured persons of higher income, giving a sum which averaged out among those new entrants at £1 1s. 1½d. for each person. It was important to bear in mind that the question of the merits of the basic capitation fee was postponed, and that the figure now offered had in it no element relating to the increased cost of living.

The Committee had before it a large number of resolutions from Panel Committees and Divisions and due attention was given to each. In a long debate it was pointed out that even though the moneys in the pool were fully allocated there were other means by which the capitation fee could be brought up to a more reasonable figure, 2s. for example, an extra halfpenny on insurance stamps, which would hardly be felt at all by the contributor; a Treasury grant, or, according to a scheme propounded by the Cheshire Panel Committee, deferred bonds. One member of the Committee was disturbed at the suggestion that the new entrants, who were of older ages, should be rated at something over a guinea a year, because he thought that that argument might be applied the other way when dependants were considered, and practitioners might be expected to take them at 6s., the fee for all insured being averaged out at 7s. 6d. On the other hand, another member found it difficult to agree that if one group of insured persons was considered to be worth £1 1s. a head, another group should be considered as worth only 6s. He thought it more likely that a higher figure would be obtained for the latter group. It was agreed that the amended offer should be reported to the Conference, but not in the form of a recommendation, and also that the Minister should be urged to reconsider his decision not to reopen at the present time the question of the basic capitation fee.

A deputation headed by Dr. Gregg subsequently waited upon the Minister, who, however, declared himself unable to go further than his amended offer of 9s. 9d., a sum arrived at without reference to increased cost of living, coupled with his undertaking to have a reassessment of the basic fee immediately after the war.

E.M.S. PAYMENT OF CLASS III PRACTITIONERS

Ministry of Health Circular 2394 of May 30 introduced special arrangements for the remuneration of Emergency Medical Service Class III practitioners specially summoned out of the normal course to a hospital at which the sessional method of payment is in operation. It was agreed between the Ministry and the Advisory Emergency Medical Service Committee that the new arrangements should take effect from March 1 last. Practitioners who may be covered by the new arrangements in respect of Emergency Medical Service work done by them between March 1 and June 1 should submit a full statement of the circumstances to the Hospital or Group Officer, as the case may be, to whom the normal claims are submitted.

A NATIONAL POST-WAR MEDICAL SERVICE

[The West Somerset Medical Club, which was inaugurated in the winter of 1939-40, appointed a special committee in the autumn of 1940 to discuss and plan a scheme of post-war medical services. The following is substantially the report of the committee and represents the views of the members of the club. The report was received at B.M.A. House on March 29.]

There is general agreement that existing medical services are unsatisfactory in many directions and that extensive, indeed sweeping, alterations are essential. That being accepted, there appear to us to be only three alternatives. One is to keep the present system but to improve it; we do not think such tinkering is an adequate remedy. The second is a whole-time State Medical Service, by which we mean a medical service centrally administered and similar in scope and type to the medical services of the Navy and the Army. While the simplicity and security of such a service are attractive features we consider its defects far outweigh its advantages. Among these are the restriction of individual incentive and the loss of independence; the serious impairment of that unfettered relationship between doctor and patient which is the basis of satisfactory treatment; individual merit cannot be accurately assessed and must be to a highly undesirable extent at the mercy of the administrative machine; medical men have their choice of locality very imperfectly under their control; any such scheme is bound to be inelastic and fail to adjust itself to local needs, which vary considerably.

The third alternative is to try and evolve a new system on regional lines, and the following scheme is the one we advocate.

Domiciliary Medical Service on a Regional Basis

First Regional Boards would be set up which would be responsible for the control of the scheme, the State being the co-ordinating and regulating authority. The regions would be based on the areas of the existing larger health authorities; we do not favour the carving out of new regional areas either founded upon a wholesale amalgamation of existing counties or grouped round the larger hospitals.

So far as possible all classes of the community would be included in contributory schemes and the basis of separate payment for work done largely eliminated. For convenience we divide the different classes of the community as follows:

A. The present group of panel patients. The existing lines of the National Health Insurance Scheme would be retained but the present financial limit would be reconsidered. The functions of the Insurance Committees would be transferred to the Regional Board, that body administering all the different groups in our scheme.

B. The dependants of insured persons, who would be included as under A. For this class we suggest added contributions from the employed head of the family, an increased one from the State, and probably a subsidy from the funds of the Regional Board.

C. Other persons and their dependants of similar financial position to those in A and B but now uninsured. They would be included in the compulsory scheme financed on the lines of B.

D. Those patients who at present come under the Poor Law. Their medical care cannot be provided under a contributory scheme; it should be paid for by the responsible authority either by a fee per attendance or on a capitation basis and with free choice of doctor by the patient.

E. The rest of the community. They would be included in a compulsory scheme which would entitle them to free medical service. They would contribute in the form of a medical tax based on income and so to payment on a sliding scale, the money going to the Regional Board. This tax would only vary up to a fixed higher income limit; all above that limit would be equally assessed according to family. The remuneration to the doctors, while still on a capitation basis, would be considerably higher than for persons in Classes A, B, and C.

It is intended that the yield of the medical tax, while not conspicuously larger than the amount which might fall upon an individual householder in any year for medical care, should be materially greater than is adequate to supply the various medical services to the classes which contribute to it. In effect, therefore, the better-off classes would be helping to finance the groups below the health insurance limit. This is an inevitable feature of any scheme, including a State Medical Service; indeed, apart from actual State contributions financed from the nation, the higher fees now charged to wealthier patients are made necessary by the inadequate payments obtained from poorer patients.

Services Available to Patients

Since a complete medical service is our aim we consider, as a general principle, that the various auxiliary services necessary for adequate diagnosis and treatment should be part of the medical benefit given to the patient without special charge. Under existing panel contracts the services to be rendered are defined as "all proper and necessary medical services, other than those involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess." This is a reasonable definition, although somewhat lacking in definiteness. Many individual practitioners will be able and willing to carry out work beyond these limitations and they should be encouraged to do so, subject to their being able to satisfy the Regional Board that they possess the necessary skill and experience. Such services would be the subject of extra remuneration. We look to men in this category to furnish some of the consultants of the future, and regard it as imperative that facilities should be made available for them to extend their experience through hospital clinical assistantships and in similar ways.

The ancillary services to be available without extra charge should include the following:

A Consultant Service.—This would normally be held at the consultant's clinic for patients sent by their doctor. A domiciliary service would be provided at the request of the patient's doctor when it was inexpedient to arrange for non-domiciliary consultations. Since some patients prefer, and even insist upon, the consultant of their choice, such consultations would not be excluded but would be the subject of a special charge to the patient, the fees received by the consultant being paid to the Regional Board. A similar principle would operate as regards hospital or other medical services.

Hospital Services.—These would include in-patient treatment if necessary, consultant advice, and such ancillary services as pathological and x-ray examinations, etc. Thus there would no longer be any need for hospital contributory schemes.

Maternity Services.—These, involving medical attendance, would be available without extra payments. Admission to maternity beds fall into two groups: (1) For some anticipated or actual abnormality requiring treatment in a maternity hospital or home; this is a public health liability and should be a charge on the health services, who decide as to the reality of the need. (2) For other than medical reasons—for example, the family or convenience of the pregnant woman, and in such cases the patient would pay the extra cost. Maternity benefit should, in our opinion, be retained.

Mental Health.—Preventive work under the Mental Treatment Act, 1930, would be under the Regional Board, so far as mental disorder is preventable this work would be undertaken through experts attached to the general hospitals and equipped with sufficient hospital beds for investigation and treatment.

Domiciliary Nursing Services.—If necessary, and if such services are available. We regard an extension of their scope as essential.

Laboratory Services.—Mostly at the hospitals, but elsewhere if available.

Dental Services.—To be included, if possible, but a scheme has not been worked out.

Consultant Homes and Rehabilitation Centres.—If these are available. It would be made an obligation on the Regional Boards to establish, if desired, in co-operation with other Regional Boards, and maintain such centres.

JULY 26, 1941

The Medical Services in the Scheme

Hospital Services.—Since contributory schemes would cease, patients' contributions would not be made, and voluntary subscriptions would inevitably be curtailed, the voluntary hospitals will have very little income. They must, therefore, look to the Regional Boards to finance and to control them. Municipal and Poor Law hospitals would also come under the Regional Boards. The actual committees of management under the Boards would, however, adequately represent all the interests concerned. Control by the Regional Board would enable all the hospitals in the area to be classified into central main hospitals, each provided with a full staff of consultants and well-equipped specialist department, and ancillary hospitals with less specialized staff and equipment. Co-ordination of beds and services of all the hospitals in the area would be essential. The only out-patients seen at the hospitals, apart from urgent cases, would be those referred by medical practitioners, if possible by previous notice so that a definite appointment could be made. Since geographical considerations prohibit regional areas from being completely self-contained some intercommunication of hospital beds and consultants would be necessary.

General Practitioners.—The scheme provides for payment along several lines. (a) Capitation payments per insured person in the groups A, B, and C. (b) Capitation payment on a higher basis for persons in the group paying the medical tax. (c) Additional payments for special services, which would include payments for attendance in connexion with confinements, payments to practitioners authorized to carry out additional responsibilities, payments per visit or on a capitation basis for the Poor Law patients, and payments for vaccination and other duties to be performed in agreement with and for the public health regional authority.

Consultants.—Consultants would only be appointed if they possessed the appropriate higher qualifications attached to their specialty, and also had special experience in it. A preliminary period in general practice would be highly desirable. Consultants would be appointed by the Regional Board and would be paid in part by a retaining fee and in part for work done. They would not be debarred from private practice, although it will be obvious that the scope for this would be limited. Their services would not be restricted to their parent hospital but made available through the Regional Board to all the hospitals within the area.

General

Every medical man should have held resident appointments for at least twelve months after qualification before starting in practice. If a practitioner wished to undertake midwifery under the Regional Board he should have practical experience beyond that required by the examining authorities. In an event the Regional Board would be required to demand evidence of adequate experience, subsequent to qualification, in an approved obstetric department. Facilities for postgraduate study would normally be provided by the Regional Board both for general practitioners and for consultants.

All general practitioners would be entitled to a retiring pension at age 65, or at 60 at the option of the practitioner but naturally at a lower figure, the scheme to be financed by the Regional Board on the usual basis of equal contributions from participants and the Board. Early death, voluntary retirement, etc., would be dealt with on the lines of other contributory schemes. A retiring practitioner would be entitled to a lump-sum payment for the goodwill of his practice, the sum to be assessed by the Regional Board on a basis fixed by the Ministry of Health for the country. Before receipt he would be required to give his successor adequate "introduction." The incoming practitioner would pay over the same sum to the Regional Board for the goodwill, and the latter would have power to lend money to incoming practitioner, the money to be repaid from payments due to him from the Board. Machinery would be necessary to ensure that the views of a doctor as to his successor, or as to a partner, received due consideration by the Regional Board.

There would be pensions for consultants in the service of the Regional Board based on the above principles. Regional Boards with available funds would be empowered and encouraged to promote research in medical problems.

Controlling Authorities: The Regional Boards

The basis of the public health areas is well defined, and apart from the absorption of small authorities would probably be retained. An efficient scheme requires close association between Regional Boards and health authorities. We therefore reject the view that Regional Board areas should be formed in conformity with existing hospitals, and suggest that their areas should correspond with what are likely to be the main public health areas of the future—that is, counties and county boroughs. This may involve some amalgamation of the smaller counties. The procedure could not well be the same for all areas, but for most of them the close liaison necessary between the Regional Boards and the health authorities could be effected by making the county medical officer of health the chief medical officer of the Board. The medical officer of health of the component county boroughs would also be closely associated with their Regional Boards.

Regional Boards would include representatives of the various local authorities in the area and of the various interests involved, such as general medical practitioners, consultants, the hospitals, and the approved societies. There should also be a direct representative of the Ministry of Health. The functions of the Boards would be wide and would include control over the panel and consultative services and over the hospital services, voluntary and municipal, but excluding the special public health institutions such as isolation hospitals, sanatoria for tuberculosis, etc. Mental hospitals would probably be excluded. Since maternity hospitals are essentially curative they should be under the Regional Boards. Other functions of the Boards would be: compliance with the general requirements of the scheme for the whole country as supervised by the Ministry of Health; general financial control of the scheme within the limits imposed by the Ministry of Health; co-operation with the public health authorities and their services.

Each Board will need its own medical inspectorate, who should invariably be drawn from men with extensive experience of general practice. They would be an essential part of the machinery to ensure that the work of the doctors was up to standard, to investigate complaints from patients, to investigate complaints from doctors, and to act as medical referees.

The Ministry of Health

While the scheme would be administered regionally, the basic factors would be the same all over the country. The Ministry of Health would settle such fundamental matters as the basis of contributions from the various insured persons, the general conditions of service of medical men, the records to be kept and the returns to be made, standards of efficiency demanded, etc. We have not attempted to deal with financial and actuarial matters, but obviously they would require special consideration, and the Ministry of Health would be intimately concerned. In particular the Ministry would be responsible for the distribution of the Exchequer contributions, a development of existing arrangements. We also appreciate that the income of Regional Boards in relationship to their commitments would be unequal, and suggest that a partial remedy for this would be varying Exchequer grants according to need. The Ministry would also serve as a Court of Appeal from Regional Boards and supervise and control their efficiency.

Relationship to the Health Services

Curative and preventive work cannot be completely separated, so a close relationship between health authorities and Regional Boards is essential as regards both the areas included and personnel. It is equally desirable that the general practitioner should be acquainted with all public health activities. While practical difficulties materially limit his active participation, the proposed scheme implies much better co-operation and a limitation of some public health work. On the other hand, it is possible in exceptional circumstances for general practitioners to undertake the charge of infant welfare clinics or be responsible for routine school medical inspection. Their assistance in midwifery and ante-natal work would continue to be of the utmost value.

WAR NOTICE

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL

WAR NOTICE Medical Officers (Lieutenant-Colonels) in Charge of Divisions

The Central Medical War Committee is asked from time to time to nominate specialists as lieutenant-colonels in charge of medical or surgical divisions. Will any specialist in medicine or surgery who desires to have his name considered for a post of this nature please communicate at once with the Secretary of the Central Medical War Committee, B.M.A. House, Tavistock Square, London, W.C.1.

WAR AND WAR SERVICE INJURIES SPECIAL MEDICAL CERTIFICATES

The following memorandum is issued by the Ministry of Health for England and Wales, the Department of Health for Scotland, and the Ministry of Labour for Northern Ireland on behalf of the Ministry of Pensions, and is a revision of the Memorandum issued in September, 1939.

1. Injury Allowances

Under the Personal Injuries (Emergency Provisions) Act, 1939, payments known as "injury allowances" may be made to persons who are rendered incapable of work by war injury or war service injury.

Where the injury causes serious and prolonged disablement the injury allowance will be replaced in due course by a pension payable by the Ministry of Pensions.

2. Definitions of War Injury and War Service Injury

"War injury" is defined in the Act as follows: "War injuries" means physical injuries (a) caused by (i) the discharge of any missile (including liquids and gas); or (ii) the use of any weapon, explosive, or other noxious thing; or (iii) the doing of any other injurious act; either by the enemy or in combating the enemy or in repelling an imagined attack by the enemy; or (b) caused by the impact on any person or property of any enemy aircraft, or any aircraft belonging to or held by any person on behalf of or for the benefit of His Majesty or any allied power, or any part of, or anything dropped from, any such aircraft.

"War service injury" is an injury sustained by a civil defence volunteer, and is defined as: Any physical injury which the Minister of Pensions certifies to have been shown to his satisfaction to have arisen out of and in the course of the performance by the volunteer of his duties as a member of the civil defence organization to which he belonged at the time when the injury was sustained, and (except in the case of a war injury) not to have arisen out of and in the course of his employment in any other capacity. It will be seen that war service injuries, unlike war injuries, are not confined to injuries caused by the enemy or in combating the enemy, but a civil defence volunteer may of course suffer a war injury while not on duty and be entitled to an injury allowance in respect of it.

It will also be noted that both war injury and war service injury, as defined above, mean physical injuries only. Injury to the brain or injury to the eyesight as a direct result of concussion, cases of shock originating from direct exposure to bomb explosion or blast in which the resulting incapacity for work starts from the time of the incident, collapse from heart failure as a direct result of an air attack, and similar casualties may be accepted as physical injuries. The definition does not cover neurasthenia and other similar sickness in which the symptoms are induced merely by apprehension and fears occasioned by enemy activity, and a war or war service injury certificate should not be issued in respect of a patient rendered incapable of work by such an illness. Such a patient, if an insured person, would be entitled to health insurance benefits in the ordinary way.

3. Position of Insured Persons under the National Health Insurance Acts

A person insured under the N.H.I. Acts who is rendered incapable of work by reason of war injury or war service injury is entitled to sickness or disablement benefit in respect of incapacity arising from that injury for a period of twenty-six weeks from the beginning of the week in which the injury was sustained, and a N.H.I. certificate on Form Med. 40 should not be issued for any period of incapacity for which a war injury or war service injury certificate is due. After the expiration of the twenty-six weeks medical sickness or disablement benefit may be payable.

4. Administration of Injury Allowances
Injury allowances are administered by the Assistance Board as agents of the Minister of Pensions, and claims are dealt with at the Area Offices of the Assistance Board. Persons making claims for injury allowances are required to produce medical certificates for incapacity for work. In the case of war injuries the first certificate must be the special war injury certificate described in paragraph 5 below, duly completed and signed, in the case of those under treatment as in-patients of a hospital, by a responsible officer of the hospital, or in other cases, including hospital out-patients, by the medical practitioner who is giving treatment. In the case of war service injuries the certificate may be either a special war injury certificate, adapted as explained in paragraph 5, or an ordinary medical certificate of incapacity for work such as doctors customarily issue to their private patients.

5. Certificates of War Injury

There are two forms of special war injury certificate—namely, a First Incapacity Certificate, supplied to hospitals and medical practitioners, and a Continuation Incapacity Certificate, issued subsequently by the Assistance Board to a person making a claim for an injury allowance for presentation to the hospital or medical practitioner for completion.

Applications for books of First Incapacity Certificates (or for copies of this memorandum) should be made, where required for the use of hospitals, to the Ministry of Health (London, S.W.1), Department of Health for Scotland (Edinburgh), Welsh Board of Health (Cardiff), or Ministry of Labour for Northern Ireland (Belfast), as the case may be; and, where required for the use of medical practitioners, to the Local Medical War Committee for the district concerned in England or Wales, the Department of Health for Scotland in Scotland, and the Ministry of Labour for Northern Ireland in Northern Ireland.

The form of war injury certificate does not discriminate between war injuries and war service injuries, but the certificates can be used for the latter purpose by substituting the words "war service injury" for the words "war injury" where the latter occur in the certificate in cases in which the insured person claims to be a civil defence volunteer who has been injured on duty.

Attention is directed to the following notes as to the completion of war injury certificates. If the patient is an in-patient of a hospital, certificate "B" of the forms should be completed by a responsible officer of the hospital, and the official hospital stamp should be affixed. In all other cases, including hospital out-patients, certificate "A" of the forms should be completed by the medical practitioner who examines the patient. In respect of each case only one First Incapacity Certificate should be issued. In the event, however, of a certificate being alleged to have been lost a further certificate may be issued, but must be clearly marked in ink "Duplicate." Certificates should not be used at first-aid posts, or for patients admitted to casualty receiving hospitals who are transferred to other hospitals after detention for a few hours only.

6. Periodical Certification

Normally a continuation certificate will be required at weekly intervals, but in the case of an in-patient of a hospital longer periods not exceeding four weeks may be covered by one certificate, and provision is made in certificate "B" of the forms for this period to be inserted by the certifying responsible officer of the hospital.

7. First Incapacity Certificate

(a) The surname and full Christian names of the patient and his precise information as possible as to the date and place of injury must be given in the space provided for at the head of the form. This part of the form should be completed by the patient or by the doctor or the appropriate officer of the hospital or other responsible person on the patient's behalf. It is important that the information should be given clearly and legibly.
(b) The description of the injury should be inserted by the medical practitioner after his examination of the patient. It will be of considerable assistance if the injury is described, where possible, according to the following codes:

Code	Notes
1. Head wounds.	
2. Injury to eyes.	
3. Injury to ears.	
4. Injury to nose.	
5. Injury to face.	
6. Injury to neck.	
7. Injury to arms.	
8. Injury to hands.	
9. Injury to legs.	
10. Injury to feet.	
11. Injury to chest.	
12. Injury to back.	
13. Injury to abdomen.	
14. Injury to pelvis.	
15. Injury to genital organs.	
16. Injury to other parts of the body.	

Injuries of more than one part of the body should be described as "multiple" followed by an indication of the most serious injury—for example, "multiple injuries (head)." If the injury cannot readily be described under the above code (for example, in the case of an injury to the brain as a result of direct concussion (see para. 2)) as precise a statement as possible should be given of the injury.

8. Continuation Incapacity Certificate

These forms are issued by the appropriate Area Office of the Assistance Board whose stamp is shown thereon. This certificate is also to be used for signing off—that is, to show the date when the patient ceased to be incapable of work by reason of the war or war service injury. If the war or war service injury no longer incapacitates the patient for work but the patient yet remains incapable of work by reason of some other disability a war or war service injury certificate should not be given, and any certificate of incapacity for work which may be required should be given in the ordinary form appropriate to the case. In the case of persons insured under the N.H.I. Acts the appropriate form would be Form Med. 40.

9. Persons receiving War or War Service Injury while Incapable of Work by Reason of Some Other Disability

In such cases a war or war service injury certificate should not be issued until such time as the other disability ceases to be the cause of incapacity for work and it can be certified that the continued incapacity for work is caused by the war or war service injury.

10. Non-gainfully Occupied Persons

Injury allowances and disability pensions are now available for persons who are not gainfully occupied. The scales of compensation for this class are at lower rates than those applicable to gainfully occupied persons and civil defence volunteers. Most of the persons concerned will be housewives, and the certificate of incapacity in such cases should be based on the capacity of the injured woman to perform her ordinary household work.

The Minister of Pensions is grateful to the medical profession for their generous co-operation in the working of this scheme, and in particular for issuing and signing certificates without fee.

Correspondence

State Medical Service

SIR.—The correspondence on the proposed reformation of the profession continues with unabated interest. One is struck with the change of tone in the letters, either through a process of selection by you or the germinating of new thought on the subject. The letter of Mr. W. Sayle Creer (*Supplement*, July 5, p. 1) appeared to me an attempt to approach the matter practically at the root of the trouble. At the other extreme there is the idealist attitude represented in the recent letter of "Ignotus" (*Supplement*, July 12, p. 4).

I am afraid to offer any practical suggestions since the whole problem is so complex, but I feel that a few criticisms might be helpful. In this respect I would suggest that a solution of our problem lies somewhere between the ideas presented in the two letters to which I have referred. Thus Mr. Sayle Creer must look for a change of ideals as well, or as part of the solution of the financial aspect, "Ignotus," on the other hand, must not ignore finance. The profession can scarcely be run on the lines of a medical missionary society, however idealistic this may be. "Ignotus" appears to be over-concerned with those "bedside-manner guinea-chasing doctors" that Dr. A. J. Cronin provided with a somewhat unmerited prominence. I suggest that these insignificant members be forgotten at present and a little more attention given to the problems of the 2,500-panel 5s. per visit man, complete with mortgage and family. These men constitute a large and youthful section of the profession. Their mortgages have to be paid, and they hope to be able to provide their children with an education suitable to produce, in many cases, doctors with the ideals of "Ignotus." It cannot be done without money unless the State provides free public school education for the children of doctors as part of its scheme.

Yes, on the whole, I am afraid Mr. Sayle Creer has struck the more practical note. We "mortgage-carriers," "Ignotus" must realize, have plenty of the service ideal (we have no alternative). We have also too much work, no time to hold old ladies' hands, and a somewhat bleak outlook.—I am, etc.,

W. J. POOLE, M.B., Ch.B.

Donner, July 13.

SIR.—I trust you will allow me to encroach again on your valuable space to reply in particular to the letter of Dr. E. K. Mackenzie (*Supplement*, July 12, p. 4). I do not quite understand Dr. Mackenzie's reference to my entering this discussion, as I am a general practitioner like himself, and, although not on the panel, I attend a fair number of insured persons. I am also interested in the general trend of our evolution, and as a member of the Association have surely the right to express an opinion, although not perhaps from the altitude of Dr. Mackenzie's pedestal.

I should like to state that I have no doubt that Dr. Mackenzie has given a true statement, as he sees it, of the way in which medical treatment is carried out in his particular neighbourhood, under both the Highlands and Islands Medical Service and the National Health Insurance Act. There is no one who has a higher opinion of the work done by the country practitioner than I, and I write from personal knowledge and experience. There are men in the profession who would do good work under the most trying conditions of service, and this has always been the case and ever will be. Dr. Mackenzie, however, makes the mistake of arguing from the particular to the general, as conditions existing in country districts, where the population is distributed over wide areas, cannot be compared with those in large towns and cities, where the population is more densely packed and where one meets with more diverse idiosyncrasies. Mr. Lloyd George recognized that what suited one district might not suit another, and this is ostensibly true in regard to colliery districts, where club practice proved to be indispensable, and certain urban communities where it was not.

Without entering further into the pros and cons of national health insurance, it surely must be accepted that the idea of a State Medical Service has originated from the failure of national health insurance as a health measure, or why the demand for a change? It seems irrelevant whether or not the young practitioner will be able to secure, two years after graduation, £500 or £600 a year and a motor car, or that an eight-hours working day may be instituted. Dr. Mackenzie may think "we are all just as keen on cash as the village grocer," but there are many in the profession who value service before cash. A certain amount of cash security is necessary, but I am of the opinion that a certain amount of struggle in the early years of practice is good for the young practitioner and for the patients who may seek his guidance.

To me the salient question in the discussion of this problem is: Will the establishment of a State Medical Service improve the health and general welfare of the community, irrespective of any financial or other benefit to the profession?—I am, etc.,

Edinburgh, July 15.

FREDERICK PORTER.

New Entrants to Health Insurance

SIR.—If the Insurance Acts Committee is to enter upon negotiations with the Ministry, it is very much to be hoped that they will proceed with great caution and not jump to the conclusion that insurance practitioners will necessarily be willing to accept service for non-manual workers with an income over £250 per annum. It was the income-limit pledge which had a great deal to do with inducing the profession to accept service under the Act at its inception. For the Government to break that pledge now without so much as a word to those to whom the pledge was given is monstrous. We have grown accustomed to such conduct on the Continent, but we have been led to understand that we are fighting to abolish such perfidy. If the argument is put forward that since the agreement was made the value of the pound has so diminished that £420 is akin to £250 in 1913, it may well be countered by the fact that there has been no proportionate increase in the capitation fee. Furthermore, it must not be forgotten that in agreeing to the proposed new income limit big inroads would be made into the capital value of private practice, which would prejudice our claim to compensation should a State Medical Service supervene. Let us be careful that the allurements of an immediate increase in the capitation fee does not lead us to "sell the pass."

As to the basic capitation fee for those already entitled to medical benefit, there are ample grounds for asking, if not demanding, an increase. It would be a mistake to press for a revision based upon the increased cost of living while other professions are in like case to ourselves. It would be much

wiser to concentrate upon the fact that the bottom has fallen out of the insurance principle in medical benefit, and nine out of ten of the cards presented to us for signature are accompanied with a request for immediate and often prolonged treatment. Also, while the new entrants to our lists are elderly and need treatment, the fresh exits are for the most part the young fit men and women recruited for the Army and other national services. We should make it clear that in seeking an increase we consider it should be of a temporary nature only, and should take the form of a bonus to meet these special circumstances which have been created by the war. We are not justified in asking the Government to raise the basic capitation fee when we are all engaged in fighting for our lives; time enough for that when the war has been won.—I am, etc.,

Caine, Wilts, July 13.

C. EDE.

Decision on Eligibility for Further Benefit

SIR,—Roughly on the analogy of the outcome of the Harnett case (when the interests of the profession were safeguarded by transferring the principal onus of lunacy certification in England to the judicial side), could not certain panel decisions be relegated statutorily to the scope of an official—namely, the Regional Medical Officer?

By this is meant that after, say, a certain number of days on the panel or repeated short periods totalling the requisite number of days all cases automatically become compulsorily notifiable by the practitioner to the Regional M.O., who makes the necessary inquiries, and whose decision then is final on the eligibility or otherwise for further benefit.

The scheme is not perhaps cast iron, and when the first notification would fall due, also subsequent notifications, would need consideration; likewise what permanent medical officials and staff would have to be created, etc. At the same time it does look as though, whilst leaving the panel practitioner pretty much where he is now, the root of certain only too well known evils in panel practice would be got at!—I am, etc.,

Life Assurance Policies: Immediate Prospects

SIR,—During the past three or four months most of the life assurance companies have held their annual meetings, and their chairmen's addresses have inevitably dealt almost exclusively with the effects of war conditions upon life assurance funds and prospects. The outstanding and, to many people, unforeseen impact of the war upon life policies is that the companies are practically restricted to War and Defence Loans for the investment of the premiums received, and can, therefore, get only 3% for their money instead of the 5 or 5½ which they formerly got (by judicious investment in open markets); and even of this paltry return a large slice goes in income tax. Consequently, as many chairmen have reiterated, the offices are finding life assurance a much less profitable affair than it used to be.

The effect of this has been to reduce the bonuses granted to with-profit-policy-holders: few companies can give more than half what they were accustomed to give, and some are giving even less than that. In respect of non-profit business, the margins of surplus are now so fine as to be barely remunerative—even non-existent. At meeting after meeting hints have been dropped that this can't go on indefinitely, which may be taken to mean that higher rates of premium are being considered by actuaries and may come into effect at almost any moment. The Medical Insurance Agency, which watches the interests of proposers and the insurance "market" in those interests, has no hesitation in advising the medical profession that raised premiums for life policies are so probable that all intending proposers would be wise to defer no longer, but take out their policies before the rates are raised against them. One may suppose that when this happens some of the existing discrepancies between the rates quoted by the offices may be narrowed and others may be widened. In either case, and whether a policy is sought at once or after the market may have risen, the M.I.A. will continue to offer unbiased and expert advice, as it has always done in the past, especially as to the relative merits in the changed circumstances of profit and non-profit policies. At the moment that advice is—Don't wait!—I am, etc.,

HENRY ROBINSON.

Hon. Sec., Medical Insurance Agency

July 4.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

Acting Surgeon Rear-Admiral C. F. O. Sankey, O.B.E., to be Surgeon Rear-Admiral.
Surgeon Commanders O. D. Brownfield and L. F. Strugnell to be Surgeon Captains.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieut. R. C. Anderson to be Surgeon Lieutenant-Commander.
Probationary Surgeon Lieut. A. R. Harper to be Surgeon Lieutenant.
Probationary Temporary Surgeon Lieuts. S. L. Townsend, J. D. Stride, P. D. Swinstead, R. W. B. Scutt, and D. J. A. Brown to be Temporary Surgeon Lieutenants.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel W. H. Cornelius, having attained the age for retirement, has retired and remains employed. (Substituted for the notification in the *London Gazette* of July 1, 1941.)

Lieut.-Colonels R. F. O'T. Dickinson, O.B.E., retired pay, late R.A.M.C., and R. K. White, retired pay, late R.A.M.C., have reverted to the rank of Major at their own request whilst employed during the present emergency.

Major L. G. Gibson has reverted to retired pay on ceasing to be re-employed on account of ill-health, and resumes the rank of Lieutenant-Colonel.

Short Service Commission—The appointment of Lieut. K. P. Brown has been ante-dated to February 1, 1937, under the provisions of Article 39, Royal Warrant for Pay and Promotion, 1940, but not to carry pay and allowances to February 1, 1938. Lieut. K. P. Brown to be Captain.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Substantive Captains T. J. Ashley, P. R. K. Lane, and B. T. Lova have relinquished their commissions on account of ill-health.

Lieut. K. C. Kershaw has relinquished his commission on account of ill-health. The name of Lieut. H. R. T. Devlin is as now described and not as stated in a *Supplement to the London Gazette* dated April 23, 1940.

The name of Lieut. J. B. O'Mahony is as now described. (Substituted for the notification in a *Supplement to the London Gazette* dated July 1, 1941.)

To be Lieutenants: P. J. MacLeod, V. W. Dix, E. Gibson, H. L. Keenan, J. R. MacNeill, C. A. Calvert, J. D. Finnean, S. M. G. McGillic, R. I. MacRae, R. G. Silver, P. J. White, G. W. Whitall, J. Zeilins, C. Cameron, A. N. Coondoo, J. Donaldson, W. J. Eastwood, A. T. Freeland, R. G. McWhorter, B. Raven, H. J. T. Ross, W. J. F. Treacher, M. Winchell, I. S. Amis, M. D. M. Bergin, J. C. Brown, F. A. Denz, C. W. Drysdale, W. Goswami, D. A. Hamilton, B. W. Knight, J. Mel D. McInosh, R. Morley, D. A. O'Reilly, A. C. Price, B. Ram, P. Smith, D. Trimble.

ROYAL AIR FORCE

ROYAL AIR FORCE VOLUNTEER RESERVE

Flying Officers P. D. B. Spence, P. B. Atkinson, and B. J. Frankfort to be War Substitute Flight Lieutenants.

Miss Marjorie M. Dobson has been promoted to the relative rank of Flight Lieutenant.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following postgraduate courses for M.R.C.P. candidates: (1) Chest Diseases at Brompton Hospital, August 25 to September 18, Mondays and Thursdays; (2) Neurology at West End Hospital for Nervous Diseases, August 26 to September 19, Tuesdays and Fridays; (3) Heart Diseases at Royal Chest Hospital, August 27 to September 17, Wednesdays; (4) Chest and Heart Diseases at London Chest Hospital, September 2 to 25, Tuesdays and Thursdays.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—Daily, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrics and Gynaecological Clinics and Operations. Daily, 1.30 p.m., Postgraduate Demonstrations. Tues, 11 a.m., Paediatric Clinic, Dr. R. Lightwood. Wed, 11.30 a.m., Clinico-pathological Clinic (Medical). Thurs, 2 p.m., Dermatological Clinic, Dr. R. I. Brain; 2 p.m., Radiological Demonstrations, Dr. Duncan White. Fri, 12.15 p.m., Clinico-pathological Conference (Pathology); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Clinical Clinic, Mr. V. B. Green-Armistead.

DIARY OF SOCIETIES AND LECTURES

DUNDEE MILITARY HOSPITAL MEDICAL SOCIETY—Thurs, 1 p.m. Maj Hugh Garland, R.A.M.C. The After-effects of Head Injuries. Medical officers and women in any of the Services, including civilian, will be welcome.

VACANCIES

EXAMINING FACTORY SURGEONS—The following vacant appointments are announced: Knowbury (Shropshire) Borough (Hampshire). Applications to the Chief Inspector of Factories, 25, Broadway, S.W.1, by July 31.

B.M.A.: Branch and Division Meetings to be Held

METROPOLITAN COUNTY BRANCH. ST. PANCRAZ DIVISION—At B.M.A. House, Tavistock Square, W.C., Tuesday, July 29, 2.30 p.m., General Meeting. P. D'Arcy Hunt. "Some Matters which require Consideration by the B.M.A. Planning Commission." All medical practitioners are invited to attend.

BIRTHS, MARRIAGES, AND DEATHS

The charges for inserting announcements under this head in the *British Medical Journal* should be forwarded with the notice, accompanied with the name of the sender, and should reach the Advertising Manager not later than 10 p.m. on Monday morning to ensure insertion in the current issue.

DEATH

GRIMES—On July 19, 1941, at 101 St. Mark's Road, London, M. S. M. Grimes, of 101 St. Mark's Road, London, who had been suffering from cancer of the rectum, aged 68 years. Buried at West Ham Crematorium on July 21, 1941.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 2 1941

WAR NOTICE

Domiciliary Visits of Public Vaccinators in Wartime

The following letter has been sent by the Central Medical War Committee to the Under Secretary of State for War:

DEAR SIR,—

The Central Medical War Committee has had under consideration the commissions now being offered to women medical practitioners recruited by the War Office.

It is noted that the emergency commissions offered to women differ from those offered to men in that they relate to the Women's Forces of the Crown, whereas those of men relate to the Land Forces of the Crown. The effect of this is, in so far as it relates to women practitioners serving with the Army, that they are not officers of the R.A.M.C. but are described as employed with the R.A.M.C. Furthermore the women receive only relative rank with the cumbersome description that it involves.

The view of the Central Medical War Committee is that women recruited for the duration of the war should enjoy the same rank, status, and title as are accorded to men so recruited.

The Central Medical War Committee would be grateful if the matter could be reconsidered, even if it involves modification of the Regulations made under the Emergency Powers (Defence) Act. If the creation of a women's branch of the R.A.M.C. would remove the anomalies the Central Medical War Committee would urge this course. There is involved a principle to which the medical profession attaches the greatest importance.

Yours faithfully,

(Sgd.) G. C. ANDERSON,

Secretary.

JULY 25, 1941.

Correspondence

Domiciliary Visits of Public Vaccinators in Wartime

SIR,—I am in agreement with the views of "Public Vaccinator" in his letter (*Supplement*, July 19, p. 9), but I do not think his proposal goes nearly far enough. The fact that about half the parents ignore his notice of intention to visit by being out when he calls makes me very dubious that they would take any more notice of his suggested card. While I have far fewer vaccinations to perform than he has, the majority have to be done at isolated farms and cottages, which usually means a special journey and often walking—an unjustifiable waste of time in wartime in a reception area.

As only about 60% of children are vaccinated in this district the Vaccination Acts are virtually a dead letter, and should, for the duration of the war, either be suspended or the onus placed on the parent to get the child vaccinated. This could be done either by the public vaccinator holding a clinic once a week at some convenient centre or by requiring the parent to bring the child to the surgery of the public vaccinator. If the country is short of petrol, as presumably it is, there is no possible justification for wasting it on domiciliary visits. I sincerely hope that the Association will take the matter up with the Ministry.—I am, etc.,

BRECON, July 19.

D. LEONARD LEES.

Capitation Fee

SIR,—The following resolution was passed with acclamation at a recent meeting held in Birmingham:

"The Local Medical and Panel Committees of Birmingham regard the increase on the capitation fee offered by the Government which now is to include non-manual and manual workers who are receiving a wage up to £420 per annum as wholly inadequate, and urge the Insurance Acts Committee to make strong representation to the

Minister of Health on that point, employing a legal expert outside the profession for the proper presentation of the case."

Many of the panel doctors in Birmingham consider we have been let down by our representatives on the Insurance Acts Committee, and ask why we are now only getting 9s. when in 1920 Dr. [now Lord] Addison, then Minister of Health, raised it to 11s. In 1921 Joynson Hicks made the absurd offer of 8s. 6d. for three years or 8s. for five years. Arbitration was demanded; the Minister of Health gave way under the threat of 98% of the profession resigning. A sad mess was made of the presentation of the case and the arbitrators only granted 9s. Dr. Addison knew the difficulties of the medical profession. He was a real friend of his medical colleagues, as my many interviews with him proved. I trust a bolder front will now be taken. The very least we should accept must be 11s., which, in the opinion of most panel doctors, is quite inadequate.—I am, etc.,

Birmingham, July 21.

F. A. L. BURGESS.

New Entrants to Health Insurance

SIR,—The medical staff of the Falmouth Hospital have instructed me to send you a copy of a letter we have sent to the Medical Secretary of the B.M.A. We would be grateful if you could publish it, as we feel that it is a matter for the profession as a whole and that immediate action is necessary.

"The National Health Insurance Practitioners in the Falmouth and Penryn areas have instructed me to address to you their united concern at the proposal to increase the income limit in respect of national health insurance to £420 per annum. They feel that the present capitation rate, always too low, should already have been substantially increased to meet the obviously increased costs incurred in carrying on general practice in wartime, and when large numbers of the fit members of our panels have been removed from our lists owing to war service. This new proposal amounts frankly to the confiscation of part of our private practice without compensation, and unless the capitation rate for such persons is based at a much higher rate we are going to be financially worse off as regards both our capital and our income.

We look to you to safeguard our interests, and to beg for your assurance that you will fight on our behalf for a just settlement."

—I am, etc.,

R. A. CAMERON, M.B., Ch.B.,

Hon. Sec. Medical Staff, Falmouth,
and District Hospital.

Falmouth, July 4.

State Medical Service

SIR,—“Let us clear our minds of cant, Sir,” said Dr. Johnson as a prelude to one of his verbal cudgellings of some unfortunate. And let us do the same thing in regard to this matter of a State Medical Service. Some of your correspondents lead one to think that the good of the patient is all that occupies their minds. If our Hippocratic Oath and the “other fellow” round the corner do not stimulate us to the proper amount of effort on behalf of our patients nothing else will. We want to think a little more about our own interests for a change, and not be afraid to do so. Our patients are “always with us,” and those whom we attend under some form of contract see to it that they get all, and often more than, they are entitled to. Who will look after our interests if we don’t ourselves? Politicians, for some reason, don’t love us. Whoever says a good word for us in Parliament unless he be a medical member? Every Minister of Health rebuts our just claim for an increased capitation fee and has done so for years.

As a profession we are hopeless in the matter of co-operation. In every district we are the sport and plaything of every dishonest person who likes to go round sampling us all in turn and paying none. Yet we won’t combine to rout the common enemy. Many doctors have no idea what an arduous business some of their profession have to make a living. They think

£10 10s.—Practitioners in Greenwich and Deptford Division area—per Dr. W. Smith (amount already sent £17 3s.); Dr. H. C. Mellroy.

Bath Insurance Practitioners—per hon. sec., Bath Panel Committee (amount already sent £11 ls.).

£7 2s.—Practitioners in area of City of Aberdeen Division—per Dr. D. W. Berry, hon. sec. (amount already sent £142 13s.); Dr. M. Esslemont 15; Dr. M. H. Kennaway £2 2s.

Per Dr. Hollis, hon. sec., Leeds Panel Committee (amount already sent £265 5s.); Dr. M. F. Percy £5; Dr. A. J. Dunlop £2 2s.

15 5s.—Practitioners in South-West Essex Division—per Dr. J. L. McKenzie Brown; Drs. Dykes and Voller.

Practitioners in the area of the Leigh Division—per Dr. J. H. Young (amount already sent £51 4s.): Dr. A. MacFaul.

£4 3s.—Per Dr. Mabel Ramsay, Plymouth (amount already sent £293 4s. 6d.)
Dr. S. Vosper £3 3s. (2nd donation); Dr. H. C. C. Reid £1 (10th donation).

\$2.25.—Cleveland Division—per Dr. G. H. Lowe (amount already sent \$9 95.)
Mr. F. S. Hubberry.

£1 1s.—Practitioners in West Norfolk Division—per Mr. J. Lewin (amount already sent £154 5s.); Dr. P. G. E. Jolley.

Per Dr. P. W. Mathew, Eastbourne.

Practitioners in Outer Isles Division—per Dr. Macleod (amount already for £16 14s.): Dr. S. Bartlett.

Practitioners in area of East Norfolk Division—per Dr. J. A. Eddy (amount already sent \$82 85.): Dr. V. Blake.

Local Medical and Panel Committees

£139 12s. 4d.—Cumberland.

163 2s. 3d.—Midlothian (4th donation).

£47 4s. 6d.—County of Ayr (2nd donation)

£31 13s. 6d.—Newsp. Mon.

Defence Bonds

Medical Staff, Harrow, and Wealdstone Hospital, £40·3% Defence Bonds
(amount already sent £2).

The following donations have come in since the above was set in type:

Individual Subscriptions

£10 10s.—Prof. Lambert Rogers, Cardiff.

£5 5s.—Anonym.

12 24.—Dr. G. B. McHutchison, Johannesburg.

221.—Medical Committee of Bishop's Stortford Hospital: Drs. Coleman, Dipple, Gammie, Gimblett, Holmes, Klaber, Morns, Sharp, and Stanley.

£8 3s.—Practitioners in the area of the Cardiff Division—per Dr. F. Y. Pearson (amount already sent £363); Dr. T. Wallace £5 ; Dr. F. O'Regan £3 3s.

£5 5s.—Per Dr. J. M. Johnstone, N. Staffs L.M.W.C. (amount already sent £786 3s.); Dr. F. N. R. Price £3 3s.; Dr. J. M. Sheach £2 2s.

£2 2s.—Per Dr. Campbell Orr, S. Staffs L.M.W.C. (amount already sent £65 18s.): Dr. A. J. Watt.

*Total: £29,690 12s. 2d. and £100 3½% Conversion Stock, and
£40 3% Defence Bonds*

CERTIFICATE FOR EXTRA MILK

The Ministry of Food wishes to correct the impression, which may have been derived by some members of the medical profession, that the procedure under the Sale of Milk (Restriction) Order to enable patients suffering from certain diseases to obtain additional milk was based on advice received from the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council. The facts are that, while the diseases specified in the Order were those recommended by the Special Diets Committee, the procedure for handling the medical certificates was designed by the Ministry itself. The arrangement by which the medical certificate passes direct from the doctor to the supplying dairyman without the intervention of the Food Office was designed to enable the extra milk to be obtained as quickly and simply as possible in the interests alike of the patient, the members of his household, and the attending doctor. The Ministry is aware that many doctors dislike the arrangement, and is discussing possible alternatives with the British Medical Association.

REGISTRATION OF DOCTORS' MAIDS

Many practitioners are experiencing difficulty in consequence of the Registration for Employment Order for women. When the scheme was first announced the Secretary of the British Medical Association approached the Ministry of Health to ascertain whether it was likely that doctors' receptionists and maids would be transferred to other duties. The Ministry's reply that the position of a registered person "will be considered in relation to the individual case, and that a person who has registered will not be considered for transfer to other work without an interview and without regard to the position which that interview discloses," was not satisfactory, but it was decided to wait until the interviewing had begun to see how the scheme was being administered. Letters now reaching the Secretary from practitioners in all parts of the country suggest that the nature and importance of the work of a doctor's maid are not fully understood by officials of Employment Exchanges. The following letter has therefore been sent to the Minister of Labour:

"I am receiving an increasing volume of correspondence from medical practitioners in all parts of the country concerning the transfer, under the Registration for Employment Order, of young women employed by medical practitioners as receptionists. In many practices the transfer of these women is causing great difficulty, and, while I do not wish to claim on behalf of the medical profession exemption for them as a group, I should like to request that individual cases should be given fuller consideration on their merits. Owing to the calling up of many medical practitioners for service with H.M. Forces the work of those who remain has proportionately increased, and the position will become still more acute as more practitioners are called up. The smooth running of a practice depends to a very large extent upon the work of the receptionist or of a maid who performs similar duties, and in the present difficult situation an experienced and efficient maid is more than ever necessary. I submit that these women are already doing work of real national importance. In some cases the officials at the Employment Exchanges have informed doctors' maids that their place must be taken by older women. This is not always practicable, and a supply of suitable older women appears not to be available. The letters I have received suggest that the nature and importance of the work of a doctor's maid or receptionist are not fully understood by the officials at many of the Employment Exchanges. The medical profession would be grateful if instructions could be issued that individual cases of doctors' maids should be given more consideration on their merits than they apparently receive at present."

E.M.S. : TERMS OF SERVICE

In January last the Ministry agreed to give not less than three months' notice of any proposed general variation in the terms of service of E.M.S. officers. In conformity with this agreement the Ministry intimated on June 12 that it did not at present contemplate any general variation in the terms of employment of Class I and Class II officers. The position of Class III officers was dealt with recently in Circular 2394.

PETROL FOR DOCTORS

The British Medical Association is still awaiting definite information from the Petroleum Department as to what will be required of medical practitioners by the proposed compulsory Order relating to logs of professional journeys. It is regretted that the promised explanation must again be postponed. A statement will be published in the Supplement when the information is available.

DOCTORS' MOVEMENTS IN AN INVASION

A number of inquiries have been received about the position of doctors seeking to visit their patients in the event of an invasion. The official attitude is that in the event of invasion it will rest with the Regional Commissioners in each Civil Defence Region to decide what arrangements are necessary to facilitate the movement on roads used by the military of private cars conveying doctors on urgent visits to their patients. All movements of vehicles other than those of the Services must be subject to the military necessities of the time and place concerned, but it is contemplated that even if doctors are unable to travel on roads required by the military it will be open to them to use other

routes for reaching those patients whom it is imperative, in their judgment, to visit. The special certificates of identity which have been provided for medical practitioners should facilitate their movement on the roads.

Medical Forces of H.M. Services
Appointments

ROYAL NAVY

Surgeon Vice-Admiral Sir P. T. Nicholls, K.C.B., has been placed on the Retired List.

ROYAL ARMY MEDICAL CORPS

Captains (Temporary Majors) M. J. Kohane and L. T. Furnivall to be Majors; Captain W. H. Hargreaves to be Major.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major R. G. Addenbrooke, T.D., having attained the age limit, has relinquished his commission and retains his rank.
Superannuated for service with Edinburgh Continent, Senior Training Corps.
— Captain J. G. McCrie to be Captain.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Second Lieut. F. S. Fiddes from General List, Infantry, T.A.R.O., to be Lieutenant. (Submitted for notification in a Supplement to the London Gazette dated December 8, 1939.)

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Captain E. Healey has resigned his commission.
War Substantive Captain H. Hillaby has relinquished his commission on account of ill-health.
Major W. B. Swete-Evans, from Temporary Commission, to be Lieutenant.
Lieut. W. Halley has relinquished his commission on account of ill-health.
L. C. McLachlin to be Lieutenant.

ROYAL AIR FORCE

Mrs. Jane G. E. Miller and Mrs. Elizabeth R. M. Wilson to be medical officers with the relative rank of Flying Officer.

ROYAL AIR FORCE VOLUNTEER RESERVE

F. Ianus to be Squadron Leader.
Flying Officers J. Jameson, A. J. Nimmo, W. H. Peck, W. S. P. R. H. Grimaldi, G. N. L. Godber, and W. C. Hoffman to be War Substantive Flight Lieutenants.
The commission of Flying Officer J. P. Griffiths is terminated on account of duty.

To be Flying Officers: F. K. Matheson, H. L. Campbell, A. J. Chigge, Sinclair, A. E. A. Cordin, W. O. Davies, J. K. Denham, W. F. Dickson, C. C. Eppel, A. H. Fairbank, M. E. Gordon, L. R. Holt, J. P. Keir, C. W. Lawson, W. I. Leslie, A. Livingston, J. McMillan, K. P. G. Meary, C. M. Miller, B. H. O'Dowd, G. C. Rae, H. L. Ross, A. A. Smith, D. Y. I. Smith.

INDIAN MEDICAL SERVICE

Lieut.-Colonel J. M. R. Hennessy has retired.
Captains J. D. Grant and J. W. Bowden to be Majors.

EMERGENCY COMMISSIONS

E. Dunsy to be Lieutenant.

COLONIAL MEDICAL SERVICE

H. R. Dive, M.C., M.R.C.S., L.R.C.P., D.T.M.&H., has been appointed Deputy Director of Medical Services, Malaya.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following Final F.R.C.S. Clinical urology at Colindale Hospital, on Thursdays, at 2.30 p.m., August 14, 21, and 28. Also the following M.R.C.P. courses: (1) heart disease at West End Hospital for Nervous Diseases, August 20 to September 10, Tuesday and Friday, at 3.30 p.m.; (2) heart diseases at Royal Chest Hospital, August 27 to September 17, Wednesday at 3.30 p.m.; (3) chest and heart diseases at London Chest Hospital, September 2 to 25, Tuesday and Thursday at 2 p.m.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, DUNCAN ROAD, W.-DAILY, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrics, Gynaecology, Clinical and Operative, Pathology, 1.30 p.m., Pathology demonstrations, 11 a.m., Pathology, Clinical, Dr. R. L. White, 11.30 a.m., Clinical-pathology conference (Medicine), 11.30 a.m., Dermatological Clinic, Dr. R. T. Brant, 2 p.m., Radiology and Diagnostic, Dr. Duncan White, 2 p.m., Clinical-pathology conference (Surgery), 2 p.m., Sterility Clinic, Mr. V. B. Green-Amstutz.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, W. Gold Street, W.-Colindale Hospital, Thursdays, 2.30 p.m., Clinical Urology.

APPOINTMENTS

EXAMINING FELLOW SURGEON: Dr. H. A. Gifford, M.R.C.S., L.R.C.P., at the Examination District (Colindale) and F. M. Smith, M.R.C.S., L.R.C.P., at the Examination District (Surrey).
General, William, F.R.C.S., Clinical Director, Birmingham Accident Hospital and Renal Institution Centre.
British, The Great, M.R.C.S., L.R.C.P., Clinical Director, Birmingham Accident Hospital and Renal Institution Centre.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 9 1941

EMERGENCY HOSPITAL SCHEME ACCOMMODATION AND FEES FOR PAYING PATIENTS

The following is the text of a circular (No. 2438) which has been sent by the Ministry of Health to all voluntary hospitals in the Emergency Hospital Scheme.

1. The Minister of Health has had under review the question of the use of private paying patients' accommodation in hospitals for the treatment of cases for whose free treatment the Minister has undertaken financial responsibility—that is, Service cases or civilian war injuries or war service injuries—and also the question of the charging of fees to any such patients for accommodation, treatment, or medical or nursing attendance in private patients' wards. As some hospitals appear to be in doubt as to their position in these respects under the Emergency Hospital Scheme, the Minister wishes to make that position clear for the future.

Treatment of Cases as Private Patients

2. It is to be emphasized that it has always been the intention of the Government that all necessary medical and hospital treatment for Service casualties and sick, for civilian war injuries, and for civilian war service injuries (Civil Defence personnel and Mercantile Marine) should be provided entirely without charge to the patient. The general arrangements made by the Ministry with all hospitals in the Scheme for the admission and treatment of the various classes of patients for whose treatment the Government accepts responsibility have been framed on that understanding.

3. The fact that this free and full service is provided cannot, of course, preclude a patient from electing not to take advantage of it, or from making his own private arrangements for treatment at his own cost as a private patient in any way he pleases (provided, in the case of Service patients, that the relevant Service regulations permit). It is essential, however, that before any patient or any responsible relative making the decision for him elects to do this, he must be clearly informed that full hospital treatment without cost is available through the Emergency Hospital Scheme, and that if he chooses not to take advantage of this and to make his own arrangements as a private patient he does so at his own expense and on his own responsibility.

4. To ensure that this is fully understood, the patient, or his responsible relative concerned, must in future be required in advance to sign a declaration in the form appended to this circular. He must have his attention particularly drawn to its contents, and the availability of free treatment must be fully explained to him.

Position of Private Patients' Accommodation in the Scheme

5. Subject to what is said below, private paying patients' accommodation in hospitals should in future be regarded as outside the Scheme. It should not be included, in making returns of bed-states or claims for bed-payments, as accommodation available for casualties. The practice of hospitals in the past has varied in this regard, and particular attention is therefore drawn to this ruling.

6. It is desirable, however, that hospitals likely to receive Service cases should have facilities for the separate accommodation of commissioned officers and those of similar ranking in the women's services. Hospitals may find it necessary also to accommodate some civilian war injuries or war service injuries separately from general casualty wards for medical reasons—that is, where separate accommodation is necessary for effective treatment of the particular case. For both these purposes a hospital may need to use rooms which are normally part of their private patients' accommodation. They may do so in the following way:

(1) In consultation with the Hospital Officer (or in the London Sectors the Group Officer) the hospital may decide to earmark for these purposes some of its existing private patients' accommodation.

(2) The accommodation so earmarked may then be regarded as available for casualties and included as such in returns and claims. The Minister will reimburse the actual cost of these beds as ascertained in the ordinary way from the "pay-bed" column on the inside of Form A.G. 136 or 138.

(3) The accommodation so earmarked must not be used for any case electing to make private arrangements for treatment at his own cost in accordance with the declaration form annexed.

(4) The accommodation so earmarked will be used for commissioned officers or similar women's rankings of the Services, or for any civilian war injury or war service injury cases for whose effective treatment accommodation separate from the general wards is found to be medically desirable; no charge, of course, of any kind may be made to such patients.

(5) With the consent of the Hospital Officer (or in the London Sectors the Group Officer) beds in the private patient accommodation so earmarked may be used from time to time, when no other private patients' accommodation is vacant, for ordinary civilian sick (as distinct from casualties or war service injuries) who want to be treated in the hospital as private patients, just as beds in the ordinary wards regarded as available for casualties can be so used in case of necessity—and the bed-state returns and claims should be adjusted in that event in the ordinary way.

(6) All remaining private patients' accommodation which is not so earmarked will, of course, be at the hospital's own disposal in the ordinary way, but will be outside the Emergency Hospital Scheme. It is this accommodation which must be used for any patients who elect to "contract out" of free treatment on the declaration form appended, and it will not rank for any reimbursement of costs by the Ministry.

Charging of Private Fees by Medical Officers in the E.M.S.

7. If a patient entitled to free treatment under the Emergency Hospital Scheme is treated in private patients' accommodation earmarked as available for casualties under the above arrangements, no question of payment by the patient of fees for medical or surgical attendance arises, any more than any question of payment for the private accommodation. These are the cases of commissioned officers or similar ranks in the women's services, or civilians transferred to that agreed accommodation because it is medically desirable for effective treatment. If, however, a patient elects to "contract out" of free treatment on the declaration form appended, and becomes a private paying patient, he is not treated in the "earmarked" accommodation and he is no longer entitled at the public expense to free medical or surgical attention in the hospital.

8. The question then arises as to how far private fees may be charged to "contracting out" patients by medical officers in the hospital who are enrolled in the Emergency Medical Service. The position of these officers is as follows. As officers enrolled as whole-time (Class I) members of the Emergency Medical Service are precluded by the terms of their contract from engaging in private practice, they are not entitled to fees from private patients. A Class II or Class III officer is not so precluded, and he may engage in private practice for fees so long as it is clearly understood that the Minister has the first call upon his services for the purposes for which he is engaged in the Emergency Medical Service.

9. The Minister will be glad if the contents of this circular are brought to the special notice of all those medical and other officers in hospitals likely to be concerned.

SERVICE CASUALTIES, INJURIES OR SICK; CIVILIAN WAR INJURIES
OR WAR SERVICE INJURIES

Declaration by patient or relative electing to arrange for private treatment.

I (name), wish to arrange for private treatment as a paying patient for myself*/my (state relationship and name of patient) at the Hospital, as from (date).

I understand that full hospital treatment, including medical and nursing attendance, is available, if I wish, free of charge and at the expense of public funds.

I understand that my decision to arrange for private treatment means that I shall be responsible for any medical or surgical fees and accommodation and nursing costs which may be incurred by me, and that I shall have no claim against the Service Departments or the Ministry of Health in respect of any fees or costs so incurred.

Signature
Date

* Strike out whichever does not apply, according to whether the patient himself or a responsible relative is making the private arrangements.

CAR REPAIRS

In recent months the British Medical Association has received many protests regarding the difficulties experienced by medical practitioners in England and Wales in obtaining essential spare parts for the repair of their cars. An inquiry on this subject was sent to the Ministry of Transport early in January, but it has proved very difficult to obtain any satisfactory reply from that Department. The Chief Medical Officer of the Ministry of Health has been good enough to investigate the position, and as a result of his inquiries the following information is now available.

The Minister of Transport considers that it is a matter of high priority in the present circumstances that the Ministry should

The areas of the Regional Transport Commissioners in England and Wales, like those of the Divisional Petroleum Officers, are identical with the Civil Defence Regions, and applications to the Certifying Officer should be sent to the following addresses:

Northern	..	41-45, Grey Street, Newcastle-upon-Tyne, 1.
North-Eastern	..	44, The Headrow, Leeds, 1.
North Midland	..	Grosvenor House, Friar Lane, Nottingham
Eastern	..	Sussex House, Robson Street, Cambridge.
Metropolitan	..	Romney House, Tufton Street, London, S.W.1.
Southern	..	Chiltern Court, St. Peter's Avenue, Caversham, Reading.
South-Western	..	Beacon House, Queen's Road, Bristol, 8.
Wales	..	Graham Buildings, Newport Road, Cardiff.
Midland	..	York House, Gt. Charles Street, Birmingham.
North-Western	..	Arkwright House, Parsonage Gardens, Manchester, 3.
South-Eastern	..	Mount Ephraim House, Mount Ephraim, Tunbridge Wells.

Insurance Practitioners and Collective Bargaining

Under these circumstances it would seem that, so far as insurance practitioners are concerned, there is only one thing to be done. We must induce the Insurance Acts Committee to constitute a thorough-going inquiry into the whole subject of collective bargaining. The expert advice of a political economist, preferably one with particular experience of trade union methods, should be obtained. The question whether it would be better to appoint our negotiators from a delegate conference rather than from a committee of representatives should be discussed passionately but carefully examined. When the report is issued insurance practitioners throughout the country should be given a full opportunity to discuss its findings and pass resolutions for future improvements in our machinery of bargaining.

Some may argue that this is a matter for the Insurance Commission. But the Commission is a body of representatives of the industry, and it is not its function to inquire into the general principles of collective bargaining. It is the duty of the Insurance Acts Committee to do this, and it is the duty of the Insurance Act Society to urge it to do so.

Some may argue that this is a matter for the Medical Planning Commission. The problem, however, is domestic and urgent. The Commissioners would no doubt be kept in touch with the various decisions and findings as the inquiry proceeded. When their own draft or interim report is published appropriate reference to the L.A.C. inquiry would doubtless be made.—I am, etc.,

J. JINGLES CAMERON.

Sir.—The suggestion that all vaccinations should be done at the surgery may be possible in towns, but would not work in rural districts. Many of my patients live six miles away, and their mothers would certainly not bring them to me, with the result that they would not be vaccinated.—I am, etc.,
South Godstone, July 27.
H. E. GUNSON.

Medical Certificates

Sir.—I, like Dr. W. R. Somerset (Supplement, July 19, p. 51), would welcome advice regarding medical certificates, especially under the Workmen's Compensation Act. The Act states that the workman in order to obtain compensation must give notice of the accident to his employer as soon as possible after its occurrence, and after notice the workman must, if required, submit himself for examination by a doctor provided and paid for by the employer. The employer is therefore responsible for procuring the certificate. The employer, taking the business view, adopts the least costly way and asks the patient to procure a certificate from his panel doctor; the patient is usually charged a small fee, and the doctor and employee are thus both exploited. So long as the employer gets a certificate which is accepted by the insurance company and costs him nothing he is satisfied. (I should be interested to know if the large insurance companies admit liability for a medical examination and certificate under the Act.)

In the past I have tried to

In the past I have tried referring the patient to the employer for the latter's authority to procure a medical certificate for which the employer will pay; this procedure was not successful and caused unpleasantness between doctor and patient. I would like some guidance as to the general mode of procedure. I think the trade union movement might be asked to take the matter up on behalf of workmen in general. The amount usually charged to the workman is small, but a penny is as important as a pound when a principle such as this has to be considered. If a verbal message to the employee does not fix the liability on the employer, surely the circumstances are important enough to justify a legal test case.—I am, etc.,

Liverpool, July 19.

SIR.—Dr. W. R. Somerset (*Supplement*, July 19, p. 9) has raised in his letter the exploitation of the profession by certain employers who demand "a sight of" the panel certificate Form Med. 40 in cases of compensation. What Dr. Somerset says is very true, and it has been my pleasure recently to collect documentary evidence of this "dodge." I find it difficult to understand how it has come into practice, because the people who are putting it into effect are doing so without the slightest intention of cheating.

By accident I have recently obtained the support of the Transport and General Workers' Union on this matter, and indeed I understand the union is going to take some action. As a matter of interest I am sending a copy of Dr. Somervell's letter to the Glasgow area secretary, Mr. Veitch.

What is necessary is a cut-and-dried method of certification to protect worker, employer, and doctor. Would anyone with any definite suggestion please communicate with me?

I am, etc.,

Glasgow, July 21, 1934.

JOHN A. MCCUSKER.

Corrigendum
The heading to the War Notes in last week's Supplement 11, should have been "Women Medical Professionals Resistant to War Effort."

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 16 1941

SPECIAL PANEL CONFERENCE LIVELY DEBATE ON CAPITATION FEE

A special conference of representatives of Local Medical and Panel Committees was held in the Great Hall of British Medical Association House, London, on Thursday, July 31. Its purpose was to consider the Insurance Acts Committee's application for a revision of the capitation fee, and the reply of the Ministry of Health thereto; also the Government proposal to raise the national health insurance income limit for non-manual workers to £420 per annum. Almost every Panel Committee in Great Britain was represented, and there were more than seventy motions and amendments on the agenda concerning these two interrelated subjects. Dr. D. G. GREENFIELD was in the chair, and was supported by Dr. A. E. Gregg (chairman of the Insurance Acts Committee). Before the discussions began the representatives stood in silence as a token of mourning for the men and women of the medical profession who had died in the service of their country.

The CHAIRMAN expressed the hope that the Conference would not resolve itself into the voicing of familiar grievances, but would concentrate on the subject-matter of the negotiations between the Committee and the Ministry and the offer made by the latter. He proposed that the first part of the proceedings should be devoted to a general discussion, after which he would select two motions expressing opposing points of view for decision.

History of the Negotiations

Dr. GREGG said that in the ordinary course of events the Committee would have already presented its case for an increased basic capitation fee on the basis of the statistics it had acquired. In February last the Ministry was reminded that, as the Committee had previously stated in the autumn of 1939, had it not been for the war there would have been this application for a reconsideration of the capitation fee, and it was also intimated that it would shortly become necessary to ask for increased remuneration on the ground of rapidly rising costs of practice. The profound dissatisfaction of the profession with the capitation fee, now more inadequate than ever in view of the increase in living expenses, was emphasized; also the insufficiency of the Central Mileage Fund to meet the increased costs of travelling. The Ministry was told that in the opinion of the Committee the capitation fee should be increased immediately by at least 2s. The reply from Whitehall was to the effect that only 13s. per insured person was available for the provision and administration of medical benefit, and that the increase in practice expenses and mileage costs was very small in relation to the insurance part of a practice. Not satisfied with this reply, the Committee strongly pressed the question of increased costs of practice, while at the same time accepting the position that until other comparable sections of the community had their remuneration increased it would be difficult to press for an advance on the ground of increased cost of living. Evidence was given of increased practice expenses, showing a 5½d. increase per insured person.

It was at this juncture that the Committee learned of the proposal to raise the income limit for non-manual workers to £420 per annum. Eventually an offer was received of a 6d. addition to the capitation fee and an increase in the Central Mileage Fund at the rate of £22,575 per annum. At a deputation to the Minister the Committee presented three resolutions.

The first expressed dissatisfaction that the new group should have been included without consultation with the Committee as representing insurance practitioners; the second reminded the

Minister that the view had been put forward on behalf of practitioners that the most necessary extension was the inclusion of dependants; and the third asked that the matter of the basic fee should be reopened.

The Committee expressed dissatisfaction that the increase of 6d. was supposed to represent, in addition to compensation for increased costs of practice, a certain indeterminate amount to "round off" the inclusion of the new entrants. The Minister was pressed to give the figures on which his calculations were based, and as a result the Government Actuary attended the next meeting of the Committee (*Supplement*, July 26) and afforded some information. At the same time a final offer raising the fee to 9s. 9d. was received from the Minister. The deputation waited upon him a second time and urged him to reconsider his decision not to reopen the question of the basic fee. The deputation was definitely told that it was impossible for any more money to be made available beyond the 9s. 9d. It was given the firm promise that after the war the question of the capitation fee would be reopened "absolutely from the ground floor," without waiting for the report of the Government body now considering the social services generally; and finally it received the assurance that in the 9d. added to the capitation fee there was nothing which was related to the cost of living. It was for the Conference to decide whether it was prepared, in view of the national circumstances and of the Minister's undertaking, to accept the offer. ("No.") He begged them not to be hasty in rejection, but if the Conference did reject it some indication ought to be given to the Committee as to what further steps it should take.

Remuneration Never Adequate

Dr. G. DE SWIET (London) said that he represented a large section of insurance practitioners who were dissatisfied not only with the remuneration but with the way in which the whole problem had been handled in the past. The capitation fee never had been adequate, but whenever the rank and file wished to bring the matter to a head they were always met with the well-worn phrase that the time was not opportune. The present appeared to be a very opportune time for many other classes of the community to improve their incomes. In December, 1939, the London Panel Committee passed a resolution that an immediate application should be made for an increase in remuneration either basically or by way of bonus, or both. The arguments for that resolution were even more cogent to-day. They had been told that they must wait until other comparable classes got an increase, but this was to overlook the fact that insurance practitioners had always formed a special class inasmuch as, to begin with, they never had adequate remuneration. Public opinion was never mobilized on their behalf, and for this he blamed those responsible for the administration of the National Insurance Defence Trust, to which some of them had subscribed for a generation. Some of the quarter of a million collected should have been spent on paid advertisements in the daily press. What was needed was "a little less half-heartedness about it all."

Dr. L. W. HEFFERMAN (Swansea) said that the Minister appeared to have solved their problem by the simple acrobatic procedure of standing the 6d. upside down and making it 9d. His committee categorically rejected the offer of 9d. increase, but considered that the obvious financial hardships of the insurance practitioner should be lessened by the granting of a war bonus. The present was not the time to open the question of a basic capitation fee. It was the time to seek a war bonus, even though it was not higher than 9d. at first. If they agreed to an

increase of 9d. in the basic capitation fee they would be less likely ultimately to get that fee altered in their favour than if they had accepted a war bonus. In the last war they had a war bonus which was increased from time to time until the original 7s. 3d. stood at 11s. This war might last five years, income tax might go still higher, motor car tax might go up to 40s. per h.p., the price of petrol might be greatly increased. Therefore the war bonus which was first granted could be looked upon as a temporary measure, to be increased as circumstances justified it, and they were much more likely to obtain an increase in bonus than in basic fee. Once this increase in the fee was accepted, the Minister would not reopen the question during the war, to whatever extent costs might rise. He knew that the present Minister had given a guarantee of post-war reassessment. But Ministers came and Ministers went. The Insurance Acts Committee must also give an independent guarantee to practitioners that the basic capitation fee would be thrashed out after the war. He criticized the way in which the Insurance Acts Committee had "stage-managed this affair."

A REPRESENTATIVE asked at this point whether the Minister had ever promised not to increase the income limit without previous consultation with representatives of the profession, to which the CHAIRMAN replied, "I think the answer is 'No.'"

Neglect to Consult the Profession is Resented

DR. G. E. ELKINGTON (Shropshire) said that the first business of the Conference should be to inform the Minister in definite terms that his recent action in introducing a Bill to raise the income limit of those entitled to medical benefit without first consulting with those who would have to do the work was bitterly resented. It had antagonized all insurance practitioners. What confidence could they have in the Minister's assurance that he would do this or that at a later date? It was clear that he attached but little value to the opinion of those who spoke for practitioners. He would not venture to treat any body of organized laymen in such an off-hand and derisory manner. In view of the national circumstances it would be impossible to carry their opposition to its logical conclusion of refusing service. Shropshire would prefer to go on treating those at present entitled to benefit at the current rate until the war was over rather than to compromise itself for a mere pittance.

DR. J. G. F. HOSKEN (Gloucestershire) said that the Committee had not made it clear whether they had considered one predominant factor which had influenced the Ministry in the negotiations—namely, the phenomenal increase in the wages of munition workers. It was obvious that the Ministry was faced with a very difficult situation. When did a manual worker cease to be a manual worker? When that question arose there was only one person who could settle the matter, and that was the Minister of Health. It had been pointed out that half a million people would come in under the new income limit. But there might easily be another half million who would come in as a result of gradual increases of wages bringing them above £5 a week. No consideration seemed to have been given to new entrants coming in in that way. He regarded what had been done by the Ministry as a "bureaucratic ramp." This Bill was not what it appeared to be; it should be fought tooth and nail, even if only on the ground that it struck at practitioners on service, whose trustees the rest of them were.

DR. R. W. RAE (Staffordshire) said that the medical services were the most important defence services of the country, and in these the general insurance practitioner was at the front continually. It was imperative in the national interest that the personnel of such a service should have fair conditions, not conditions of exploitation. Previous to the last Court of Inquiry, when an insurance doctor urged that with the increasing range of service and the generally high standard maintained some revision of the terms of service could not in elementary justice be longer delayed, a senior official—a regional medical officer—replied: "Twopence a week is what you are going to get. You must scale your work down to twopence a week, and if you want to do better work you must do it as a hobby." In the interests of the community as well as of the profession, the basic capitation fee, or rather the range of panel service and contract, should be readjusted.

A Question of Eligibility

DR. J. C. PEARCE (Norfolk) said that this was an occasion for boldness, and he invited the Conference to consider three facts which bore on the situation. In the first place there had recently been a very exhaustive examination of the income of the whole community, including insured persons. Secondly, ever since the Insurance Act came in the Minister of Health had delegated the administration of that Act to the Approved Societies. Thirdly, there had been almost inexplicable haste on the part of the Minister to get this matter of the increased income limit settled. He suggested that there was evidence that many of the insured persons of the present day were ineligible owing to the fact that they were not within the income limit of £250. He asked them to throw their minds back to their own practices and consider the patients who had come to them twenty years ago as beginners and were now foremen and managers and so on, but were still insured persons. These in aggregate came to a very great number, and technically they were not eligible for insurance benefits. The Approved Societies were administered by excellent business men who could see the significance of this in a flash. They realized that if the evidence for this became available to the public these people would have to go, in which case the Societies would lose millions of money in weekly contributions, or else something would have to be done with the medical profession. In these circumstances the only thing was to raise the income limit, but the cards must not all be shown at once, otherwise the medical profession would have an unanswerable argument for an increased capitation fee. Therefore what was done was to suggest that the profession should become responsible for a new class of insured patients—those near the borders of the present income limit. Strings were pulled at the Ministry of Health, and the Minister, having slammed the door on the question of an increased capitation fee for practitioners, opened it again a little way and said, "We are proposing to put up the income limit, and if you agree to that we will have an investigation of the whole 'show' immediately after the war, and as a bribe I will give you an additional 6d." The Insurance Acts Committee looked coldly on this, and before the Conference was called the offer was raised to 9d., and at the same time the Bill to raise the income limit for non-manual workers was introduced into Parliament and passed its second reading. What cards did practitioners hold in their hands? First, there was the urgent need that this new legislation should carry the consent of the medical profession. Again, the Minister had his own axe to grind: he wanted popularity with the proletariat and to take another step in the direction of State medicine. What was on the other side? True, they had got their 9d., but there was nothing to prevent the Minister from taking the 9d. off again after the first quarter's pay. The Norfolk Panel Committee suggested that the Government's proposal to raise the income limit should be subject to the condition that the capitation fee was simultaneously increased to a rate of not less than 12s. per annum. This figure had been carefully thought out. One of the essential things to go for was a reapportionment of medical benefit out of contributions. As long as the total sum stood at 13s. the Government could not afford to give them more than 9s. Twelve shillings was not an unreasonable figure considering that in 1914 the fee was 7s. 3d., which would now be equivalent to 14s. 6d., but the 12s. did not represent a war bonus which could be taken off when the war was over.

Financial Position of Insurance Practitioners

DR. GORDON WARD (Kent) said that he came from a county in which most of the coastal towns and of the large towns were in the county were depopulated, and the question is between 8d. and 9d. made a good deal of difference to practitioners. A number of evacuees had been treated, some of them at his including drugs, but others had no money and had to be treated free. Practitioners had had a spite of new certificates for first treatment of Home Guards, and many military cases had to be treated for—these were some of the extra conditions which had been imposed upon them, and all the while they were suffering from the usual encroachments. The Minister of Health the other day had invited that for 100,000 military and for 100,000 civilian cases went to civilian. That was true, and they did not get the government of practitioners, who, in addition to the fact that

pay for the clinics, forfeited the money which would otherwise have come to them for treating these people. The hospitals were under the E.M.S., and an E.M.S. official told him only a few days previously that it was their policy to oust the general practitioners from the hospitals. During the war much of his own private practice had been switched over to the insured part, because people who had been in comfortable circumstances were now doing quasi-Government jobs of one sort or another. The "black-coated medical profession" were harder hit than many of the people they had to attend on an insurance basis. Dr. Ward exhibited a chart showing curves from 1914 to 1941 for cost of living, capitation fee, and insurance practitioners' obligations. The work had increased by 100%, the cost of living by 100%, the fee by only 28%, and they were offered 9d. He called for the resignation of the Insurance Acts Committee (he called them "worms") unless they were prepared to fight.

Dr. P. C. MATTHEW (Cornwall) said that his committee, while dissatisfied with the basic rate, suggested that they should carry on at that rate during the war, accepting the Minister's offer of 6d. increase to cover acknowledged increases in practice expenses, but that his further offer of 3d. should not be accepted because it might prejudice their case afterwards.

A "Niggardly" Offer

Dr. A. W. WESTON (Dudley) said that on the statistical argument an offer of 9d. was quite ridiculous. If the Committee went back on its demand for 2s. it would be showing a weak hand. He also pointed out that practitioners originally had agreed to accept a certain number of people at a certain rate, and when to that class was added another the bargain was broken. The new entrants, who had previously been private patients, would expect as insured patients the same attention as in the past: they would expect a visit when they had a whitlow or a slight sore throat instead of attending at the surgery. The Government could go to Parliament and set up legislative machinery to bring into insurance persons with incomes up to £420, but they could not see their way to increase the amount available for practitioners because it meant asking Parliament for more money. He would sooner have nothing said about increased costs of practice, and regard it as a contribution to the war effort, than be put off with this niggardly amount. His committee suggested the absolute rejection of the offer of 9s. 9d. They agreed that the revision of the basic capitation fee should not be pressed at the moment.

Dr. HOWIE WOOD (Isle of Wight) said that this problem should be tackled under two heads—the first with regard to the new group of entrants, and the second, the existing insured population. With regard to the first his committee felt that the Government had not quite played the game with the medical profession in the way that this proposal had been sprung upon them without prior consultation. If this group was to be taken into National Health Insurance it meant a diminution of private practice and a suitable capitation fee should be paid for them; his committee suggested not less than £1 per head. As for the main body of insured persons, at no time did the medical profession consider that it had been adequately remunerated with a capitation fee of 9s. In his area at any rate it was felt that 9s. was an inadequate fee having regard to the amount and standard of work given by practitioners. Factors which justified increase in an upward direction were: (1) increased work, including an increased number of forms to be signed and so forth; (2) increased practice expenses; (3) the very important fact that the removals now taking place from their lists were good healthy lives, while the new entrants were many of them elderly and either required medical treatment within a few weeks of coming on to the list or were liable to do so during next winter. If this was an insurance scheme they were supposed to have some jam to go with the bread-and-butter, but the jam was leaving them. While they did not wish to hold a pistol to the head of the Government, they were entitled to expect recognition of the fact that they were doing a good job of work and had a right to an increase.

Dr. A. SMITH POOL (Glasgow) said that his committee felt that the Government offer should be refused. The Minister was taking advantage of the present emergency to introduce a new class of insured persons. This might be the thin end of the wedge of a State Medical Service based on national insurance

with all the disadvantages of lay control and bad working conditions—a twenty-four-hour service at the lowest possible remuneration. The Minister's offer of 9d. was an indication of the complete failure of the negotiating machinery to secure an increase of the basic capitation fee. By accepting 9d. they would be agreeing to the principle of the admission of new classes of insured persons without consultation with the profession. He asked them to contrast the position with that of salaried officials in industry. In the coal industry some of the larger companies had increased salaries above the £500 level by 10%. Even the British Medical Association had recommended an increase of private fees by 20%.

Dr. H. M. GOLDING (Bristol) said that Bristol was favourable to the acceptance of the Minister's offer of 9s. 9d. on conditions. One condition already accepted was that immediately after the war there should be a full inquiry into the basic fees. Bristol wanted the further condition that the award then made should be retrospective to January 1, 1942. This was on the same lines as deferred payments. It was also necessary to clarify the expression "after the war." Did it mean the signing of the armistice or the ratification of the peace treaty? A more definite term would be "at the conclusion of hostilities."

The "Worm" Turns

Dr. E. A. GREGG said that he would be the last to criticize any representative for speaking with vehemence, even though at times in that debate there had been more vehemence than thought. When he looked at the Insurance Acts Committee he was accustomed to say to himself: "These are the representatives of insurance practitioners whom those practitioners by their own choice have sent from the various localities to put forward their views." If they had chosen "worms," why had they chosen them? One speaker had said that the Insurance Acts Committee was recommending the Conference to accept something. That was entirely inaccurate; the Insurance Acts Committee had not recommended any course to the Conference. They had merely reported what they, the "worms," had succeeded in doing to the best of their modest ability. They had told the Minister of the difficulties and burdens of insurance practitioners, and while the Minister had stated that he could not as yet increase the basic fee, he had given them the assurance that the additional 9d. was not a war bonus so far as cost of living was concerned, and the Minister had been told by them that when the cost of living came to be considered in respect of any class of the community comparable with insurance practitioners "we will be there." As a result of statistical information which the Committee had accumulated—and they had figures which could not be gainsaid—the increased practice expenses at the present time represented 5½d. for each insured person. By virtue of the fact that the Minister was proposing to introduce a new class into insurance, he was offering them 3½d. more, making a capitation fee in relation to that new class which was quite considerable. He (Dr. Gregg) could not pretend that he was pleased at the way in which it had been done, and the Minister had been made acquainted with their feeling in the matter. Several members of the Conference had declared that they would not accept the offer. "Well and good, do not take it. It is for you to decide, and it is for your decision we have brought it forward to-day."

Motion for Acceptance under Protest

Dr. J. A. PRIDHAM (Dorset) moved:

That this Conference, in view of the national emergency now existing, cannot do otherwise than accept the Minister's offer of a capitation fee of 9s. 9d., but in doing so wishes to record an emphatic protest against

(1) The inadequacy of the offer, and

(2) The fact that a new group of insured persons has been admitted to insurance without previous consultation with the profession.

He said that this resolution was adopted unanimously after discussion at a well-attended meeting to which all insurance practitioners in his county had been summoned. It was not pressed upon them by the official representatives. They realized certain hard facts, the first of which was the existence

of a national emergency. The Minister had said that in making his offer he had not considered any rise in the cost of living. That was an issue they could not press at the moment. The Minister had refused to open up at the present time the question of the basic capitation fee. Was it to be supposed that if it was decided to open up that question they would get support from the rank and file? They would require a 90% response to be effective; they would not get it in Dorset, and he doubted whether the rest of the country would think differently. Would the present atmosphere be helpful to a reopening of the capitation fee question? He thought it would be the worst possible moment. At the same time Dorset believed the present offer to be inadequate, and also regretted that the new group were being admitted without previous consultation with the profession. He would also like the Committee to make sure that the Minister's promise to review the situation at the end of the war was binding on future Ministers.

The CHAIRMAN, in reply to a representative who asked why the Dorset motion had been given precedence, pointed out that seventy-four resolutions had been sent in, and these had been scrutinized by an Agenda Committee, which had selected two—the other was by Birmingham—expressing diametrically opposite points of view, so that by voting upon them the opinion of the Conference could be most conveniently crystallized.

Dr. J. KERR (Cheshire) said that his committee still adhered to a resolution it proposed at the Panel Conference in 1938 that the minimum capitation fee should be 15s. The arguments then put forward were even more cogent to-day. During the last twenty-eight years first the Insurance Commissioners and then the Ministry of Health had adopted a policy of peaceful penetration, with an annual output of new regulations and new responsibilities for practitioners, resulting in a greatly enhanced service, to which the present capitation fee bore no adequate relation. When the fee was first fixed in 1913 at 7s., with the "floating 6d.," it was the meanest and most stingy rate of remuneration paid for medical services, but the 7s. 3d. average of 1913 had now become after nearly thirty years only 9s. 9d. Insurance practitioners had always been the drudges of the medical service. The bureaucrats at the Ministry had shown little appreciation of the skill and judgment shown by those carrying out the insurance service. They did ask that the remuneration should bear some relation to their responsibilities. Cheshire had put forward a suggestion that in addition to the capitation fee there should be a system of deferred payment by means of bonds maturing after the war. His committee had greatly resented the action of the Ministry in not consulting the Committee before launching a scheme which might gravely disturb the financial stability of many practitioners.

Refusal of the Offer Urged

Dr. A. BEAUCHAMP (Birmingham), who had a motion on the paper that the Minister's offer be refused, said that he would prefer to speak and vote against the Dorset motion. The representative of Dorset had said that in view of the national emergency they could not do otherwise than accept the Minister's offer. Why? Were they quite sure that justice to the panel doctor—and that was all they asked for—would upset the war effort? The previous Sunday night a well-attended meeting of insurance practitioners was held in Birmingham, and the resolution to reject the offer was carried unanimously. Had there ever been a time when they could say to the Ministry, "We are not playing at your game"? At the present moment probably most insured persons, if practitioners refused insurance service, could afford to pay private fees; those who could not would have to be treated for nothing or taken into the Public Medical Service. He had always thought that there was an understanding, if not an agreement, that the Ministry should consult with representatives of the profession in such circumstances as had recently arisen. Apparently he was wrongly informed, but in all decency this should have been done. At the meeting in Birmingham he was asked what guarantee they had that the Minister would implement his promise after the war. He replied that he understood the Committee was satisfied on that point. The meeting was not reassured; they had not faith in the Insurance Acts Committee. He asked the Committee to regard this matter in all its implications. They were told there was no money with which to pay a higher capitation fee, yet from the report of the remarks of the Government Actuary at

the meeting of the Insurance Acts Committee in the current Supplement it appeared that money was being paid from the pool to enable Approved Societies to make war payments to their staffs and institute A.R.P. services. The increase of 8d. represented nothing like the increase of private fees recommended by the Association.

Dr. DANBY COGAN (Northampton) also urged rejection of the Minister's offer. He pointed out that three or four million first-class lives had been removed from the care of National Health Insurance by going into the Forces; they were replaced by a number of second-class lives; people who had been unemployed for a considerable time, women who had never been employed before and who were working long hours on a second-rate diet. Practitioners had dependants of members of the Forces on their hands; they did not grudge their attendance, but the long hours of service entailed by present-day practice ought to be remembered. In the black-out the doctor's duties were more arduous, and if next winter was anything like the last two a great many of the elder ones among them would never see the award of the increased capitation fee. Dr. F. N. C. COZENS (Kent) said that he was charged by his committee to ask the Conference to reject the Minister's terms. They were inadequate to the extent of an insult. Unless practitioners obtained 2s. increase he suggested that they should not co-operate in treating this new class of patients who had been foisted upon them.

A Summing-up

Dr. H. G. DUN said that there had been a good deal of speaking on aspects of the problem which were not germane to their present consideration. Nobody objected more strongly than he to the way in which the Ministry had approached the matter and the scant courtesy it had shown to the Insurance Acts Committee. But he wanted to analyse the situation as it appeared to him. They should have been consulted with regard to the admission of another group of insured persons, and they had previously urged that the first group to be taken in should be the dependants of the present insured. But it was the business of the Government and Parliament to decide what sort of people should be provided with services of different kinds and what standards of income should be applied. The point at which practitioners came in was with regard to the conditions under which they rendered the service. The Committee had done what was possible by personal negotiation to get an increase in the monetary value of the Minister's offer. The offer included, first of all, everything that they had asked for in the matter of mileage and also in the matter of increased practice expenses. In addition a sum of 3½d. had been given, spread over the whole insured population, which made a very substantial capitation fee for the new group now being admitted. He himself was all against the admission of the new group because it consisted of people who, he thought, should pay for their medical attendance in the ordinary way. But the offer was 9s. 9d., and the Conference had to consider whether it should be accepted. He believed that if they pressed for another 3d. or 6d. they would be standing in the way of reconsideration of the capitation fee at the proper time. The Minister's offer to review the whole position at the end of the war had been made sufficiently publicly to be imposed on his successors without any difficulty. Hitherto in their negotiations they had always had to meet the argument that the amount of money available—namely, 13s.—did not admit of any rise of the capitation fee. This amount had now been raised to 14s. 6d., and although it did not appear that they were going to get more than 9d. of the additional amount, the Minister had said that he would undertake not only to have the offer reconsidered at the end of the war, but to introduce a bill with the necessary clauses to give effect to any award which was then made. He hoped that the Conference would think that on the whole it was the wiser course to deal with the present offer as a matter of business in view of the circumstances of the time, without prejudicing the position in any way for the future.

Dr. J. BLOX (Glasgow) said that Glasgow was not prepared to accept the Government offer, and was also doubtful as to the way in which the Committee had handled the offer. This was another instance of "appeasement."

Dr. L. W. HERRING (Glasgow) said that Glasgow was not prepared to accept the offer on the ground of inadequate remuneration, and asked the Committee to press a strong case for a war bonus for all

the financial hardships of insurance practitioners, meanwhile postponing until the end of the war the consideration of the basic capitation fee. The CHAIRMAN refused to accept this on the ground that it was not an amendment at all, but another motion altogether.

Decision of the Conference

The Dorset resolution accepting the Minister's offer under protest was put to the Conference, and on a show of hands was declared carried by 97 votes to 79. More than 20 members demanding a division, the names and votes of the members present were taken and recorded, and the result was as follows: in favour, 98; against, 79.

Dr. N. E. WATERFIELD (Surrey) moved, and it was agreed by the Conference, that there be added to the motion just carried:

"and their acceptance is without prejudice to the consideration of their claim to a satisfactory increase in the basic capitation fee, and without prejudice to their claim to a cost-of-living increase when such increase is given to comparable sections of the community."

War Bonus Advocated

Dr. G. DE SWIET (London) moved a rider to instruct the Committee to press immediately for a war bonus to meet the financial hardships of insurance practitioners. He said that there was evidently a large minority who were not satisfied with the acceptance of the mere 9d., and this rider would meet their case.

Dr. WATERFIELD (Surrey) and Dr. C. L. BATESON (London) protested that this rider was an attempt to reverse what the Conference had just decided. Dr. R. DAVIDSON (Nottingham) hoped that the 9d. would be referred to entirely as a war bonus. The question of varying rates of remuneration for attendance on different classes of the community brought in an important matter of principle, which could hardly be decided at the present time, and the immediate difficulty could be overcome by regarding the 9d. as a bonus. Dr. DE SWIET said there was no intention to go back on the decision of the Conference. The idea behind his rider was to encourage the Committee to go on endeavouring to get some improvement in the remuneration, whether by way of bonus or anything else.

The rider was lost.

Dr. F. M. ROSE (Preston) moved a resolution deploring the fact that the Committee in its negotiations with the Ministry had never yet obtained an adequate capitation fee. He said that in 1912 the capitation fee was 7s. with the "floating 6d.," averaging 7s. 3d. Its changes since then had been more or less parallel with the changes in cost of living, taking not the basic cost but the proportion which applied to the middle class. In 1941 the capitation fee was 9s., which was 24% above the fee in 1912, and the increase in the adjusted cost-of-living figure was similar. But the original 7s. was far too low. Had it been 10s.—a reasonable sum at that time—the fee now, with commensurate cost increases, would have been 15s.

The motion was agreed to, as also was a motion by Surrey, that in the event of a new class of entrants bringing the number on a practitioner's list to a point in excess of that at present allowed, such new entrants should not be taken into consideration in computing the total on the list for the purpose of limitation.

Another motion, in the name of Leeds, was carried, emphasizing the regret already expressed by the Committee that the higher income group rather than dependants of insured persons should have been included in the scheme.

A motion stood on the paper in the name of Denbighshire, but the representative was not present to move it, drawing attention to "certain valuable points" in the literature circulated by the Medical Practitioners' Union on the inadequacy of the capitation fee, and urging that the British Medical Association and the Union should collaborate in presenting a case to the Government. The CHAIRMAN formally moved this in the representative's absence, and it was negatived by a very large majority.

It was agreed to refer to the Committee for consideration a motion in the name of Leeds that the objective of the National Insurance Defence Trust—namely, two million pounds—should be increased as soon as possible.

Bristol desired the Conference, in agreeing to a postponement of a complete review of the basic insurance capitation fee until immediately after the war, to do so on the condition that the award then made should be retrospective to January 1, 1942. This was accepted as a reference to the Insurance Acts Committee. Dr. GREGG said that the Committee would do what it could, but the prospect of success was poor.

Dr. JULIUS LIPETZ (Edinburgh) summarized the sense of certain motions by Liverpool, Leeds, and Devonshire, by moving that the Conference affirm that the immediate necessities of national health and the war effort demanded the inclusion of dependants of the present class of insured persons; also that Panel Committees should call meetings of practitioners in the various areas to discuss this point. He said that the profession would be faced before long with some form of State Medical Service; if they left this to be imposed upon them from above, as the inclusion of the new group had been, they would be in a very uncomfortable position.

This was carried.

The final motion of the Conference, proposed by a representative, affirmed that the Insurance Acts Committee had the loyal support of the Conference and was carried *nem. con.*

The Conference lasted three and a half hours.

PLANNING FOR DENTAL SERVICES

In his address from the chair of the Dental Board at its recent session Mr. E. L. SHERIDAN, after referring to the appointment by the British Medical Association of a Medical Planning Commission, said that the British Dental Association, the Incorporated Dental Society, and the Public Dental Service Association had suggested that the Dental Board should take steps to set on foot an inquiry into the adequacy of dental services, the remedying of deficiencies, the constitution, powers, and duties of the Dental Board, and the practical working of the Dentists Acts in view of post-war conditions. Some of these questions were within the province of the Board, and others were outside. The Board agreed to inform the dental organizations that it was in sympathy with their desire to review every aspect of professional activity, but that certain of the matters did not fall within the statutory functions of the Board. It was added that the Board was occupied with schemes for dental education and research to come into force after the war, and would welcome any recommendations which might be brought before it as a result of the inquiry which the dental societies proposed.

The Board appointed a Clinical Investigation Committee, under the chairmanship of Prof. W. H. Gilmour, to lay down the lines for investigations which could advantageously be made the subject of clinical research with a view to the simplification of methods for the conservation of the teeth and the maintenance of the associated dental tissues in good health. Two grants each of £150 a year for five years were offered by the Board to the London Hospital Medical College in aid of the salaries of the demonstrators in operative dental surgery and clinical dental prosthetics in the London Hospital Dental School. The renewal of a grant of £500 a year and of two grants each of £250 a year for five years was offered to the University of Leeds in aid of the salaries of the professor of dental surgery and warden of the dental school, an assistant to the professor, and a whole-time demonstrator in prosthetic dentistry. The renewal of grants of £500 a year and £250 a year for five years was also offered to King's College, University of Durham, in aid of the salary of a professor of dental surgery and director of dental studies in the dental school at Newcastle and of a lecturer and tutor in dental mechanics and prosthetics in the same school.

The King Edward VII Welsh National Memorial Association has passed a resolution urging that all recruits should be radiologically examined and that medical boards should refer any recruits with a family history of tuberculosis to an officer of the association. This resolution reflects once more the growing concern among public health workers regarding the large number of men passed as fit for the Services who are subsequently discharged suffering from tuberculosis.

Correspondence

State Medical Service

SIR.—While a State Medical Service might suit me personally quite well, I feel sure that it would be to the disadvantage of the public and the profession in the long run, for I think that Government control would in time inevitably spoil that intimate relationship between doctor and patient which is essential to the best medical practice. I am not perturbed that the majority of the younger members of the profession seem to favour the idea and also those who are accustomed to institutional medicine. It is but natural that these should wish to reproduce the conditions in which they are brought up, and consider that centralized clinics, resembling in some way hospital out-patient departments, are the ideal. It is probable that in such surroundings the textbook diseases of their patients might be treated more thoroughly and conveniently than in their own consulting-rooms, but it is quite certain that they would never treat that disease from which such a large number of patients suffer and which they never disclose in unfamiliar surroundings or to one with whom they are not well acquainted. Actually it takes a man quite a long time in general practice to realize what his job is. He has been accustomed in hospital to see isolated examples of disease in standardized surroundings, rather like a "still" in a cinematograph film, important—indeed essential—for the meticulous study of the disease; but in general practice he sees the whole film with its changing background acting on the principal actor—the patient—moulding, modifying, revealing, or concealing the morbid processes at work. It is a much fuller picture than that seen in hospital, strange alike to the hospital teacher and his newly qualified students, and often confusing enough to one who has spent his life unravelling it. This is the G.P.'s battleground, and if we would fit him for it he certainly should have practitioners of mature experience to teach him. When that happens the younger element will no longer sigh for a State Medical Service; but once one is established we shall all sigh or cry in vain. We should not do away with what is good in the old order before we understand what it is or why it arose.

In the same way the results of the Gallup survey are important, but they should not be taken at their face value. What they show is a real dissatisfaction with medical practice as it is, but very few of those who expressed an opinion can have had a real comprehension of the issues at stake. In all probability it merely expressed a wish to escape doctors' bills and a feeling that the doctors would be all the better for being under more control. If the question had been whether they would like to be under the control of a State Medical Service the answers would probably have been significantly different, yet this control of the patient is possibly the most attractive thing in the eyes of the doctor.

So all is not well with general practice, and I think that the two worst things about it, which react equally badly on patients as well as doctors, are its commercialism and competition, which naturally tend to foster isolation, jealousy, criticism, and suspicion, instead of that feeling of brotherliness which should exist among members of a great profession. I think this could very largely be removed, with great benefit to the public as well as to the doctor, if the national health insurance authorities would refuse to acknowledge isolated doctors, and say that modern conditions sufficiently good attention to the insured population can only be afforded by a group of doctors—say, not fewer than eight, and preferably more in congested areas. This would inevitably lead all the doctors in any area to form a partnership for panel practice, and so, in practice, for all types. It would give panel patients in effect free choice of doctor in a way they do not have at present and would leave private practice practically undisturbed. It would mean that practice in every area would be carried on as a co-operative affair, which would evolve in the way best suited for that particular locality and avoid the regimentation that is almost inevitable in a State Medical Service. There would probably have to be special arrangements for the sparsely populated rural areas and undesirable residential districts such as mining villages. Perhaps the easiest way of rectifying this would be an increased capitation fee in districts which were found to be badly served, and in rural

areas boundaries might have to be drawn between practice groups.

Such a scheme would keep our fate largely in our own hands, allow us freedom of residence in whatever area we desired, and freedom, within wide limits, to choose associates in our life's work. It would ensure that continuity which is so desirable in family practice, and avoid the constant change of doctor as the latter ascended in the hierarchy envisaged in a State Medical Service. At the same time a group of eight doctors or more should be able to arrange among themselves for holidays, and include sufficient young ones to offset any disability of the older ones for night work, etc. It would also enable doctors in the group to specialize to some extent along their natural line of surgical, industrial, institutional, or other work; and, as nearly every group would contain within itself one or more doctors on the staff of the local hospitals, it would in practice open these hospitals to all the members of the group acting as their assistants or deputies. The main thing is that each group of doctors could be trusted to see that their colleagues developed in ways which were really beneficial to the activity of the group, as a whole and so to the benefit of the public at large; while centralized financial and clerking arrangements would relieve the doctors of much tedious bookkeeping, etc. They should be able between them to raise enough capital to equip their own special clinic for minor accidents or special investigations, leaving the really specialized work for patients to be sent to large hospitals, where such work will always be most satisfactorily performed. I think that a proper scheme for the community must certainly include dependants and pensioners, etc., as insured persons, and as a corollary of this it would be reasonable for the Government to insist that each group of practitioners did, in fact, provide adequate facilities for attendance and consultation, together with any necessary supervision to see that this was carried out.

If, unfortunately, a State service should be forced upon us and the question of remuneration come to the fore, I think it is a pity that several of your correspondents have suggested that Dr. Pybus's scale of salaries seems more than we can expect. If a State service is to be maintained by the contribution of the doctors as well as the rest of the community, it surely cannot be contended that this contribution should be less than that already paid to the doctors by the people at large. If, as some have suggested, consultants should be willing for the sake of the general good to forgo some of their princely incomes, I feel sure that the latter would do so more willingly if they knew that the surplus of their incomes was going to sweeten, as it would, the incomes of many of their poorly paid brethren. Only the income tax officials have all the figures required, but I fancy that the income of all practising doctors before the war would easily sustain those rates of remuneration suggested by Dr. Pybus.

As regards this question of finance, several doctors have expressed views on the real nature of money and the capacity of the State to pay what it likes, but I have seen no reference to the fundamental fact that the face value and real value of money are two very different things. What we work for is a standard of living rather than so much wealth, and doctors doing the same work in State service should be entitled to the same standard of life. This implies that the actual salary they receive must bear some relation to the number of dependants they have to support. It is of little value to a man at the age of 60 to be drawing £1,500 or £2,000 a year, while such an income would have been of enormous help to him and to the community when he had his children to support and educate. His basic salary might well increase as he grows older, but the actual money he draws should take account of his social and other responsibilities. In any scheme of payment for a State Medical Service we should at least insist that these basic facts should be considered. If we can establish such a scheme of remuneration for ourselves we shall, by giving a model to other State services, have perhaps in the long run done more for a contented and healthy population than all our purely medical efforts put together.—I am, etc.,

W. N. LEAK.

Winsford, Cheshire, July 31.

SIR.—I imagine your correspondents realize that all their letters in favour of a State Medical Service are joyfully studied by the Ministry of Health and then carefully filed. Before we sell our birthright by expressing ourselves in favour of a State service we ought to remember certain great disadvantages.

(1) *Salary and Pension.*—The Minister will no doubt be advised to offer a salary similar to that paid to officers performing analogous work in other Services such as the Army and Navy. This will probably be in the neighbourhood of £500 a year. The pension, always an attractive red herring, will not be more than half the salary, and has, of course, the serious drawback that it is only paid during the practitioner's lifetime and makes no provision for his wife and children should they survive him.

(2) *Promotion and Removals.*—Promotion and increased pay in the service will almost certainly involve transfers about the country. A Civil Servant usually moves every five years or so, and the removal allowance (as every Civil Servant knows) is never sufficient to cover all the expenses incurred. Frequent removals are a serious drawback to the practitioner, as they imply that a man spends his working life in a series of lodging houses none of which can ever be his settled home. It means the continual breaking up and renewing of all social contacts. It involves serious expense in educational arrangements for his children, as his salary will not be sufficient to permit a man to send his children (if any) to boarding schools or universities.

(3) *Personal Freedom.*—A doctor at present has considerable personal freedom to arrange his time to his own convenience. He fixes his own consulting hours, his own visiting hours, and his hours of leisure. He even fixes his own holidays. Under a State service his hours of work are fixed for him, and his holidays, though generous, will be allotted to him after senior officers have had their choice. His freedom will disappear, and he will even have to keep his bus tickets. I need say nothing about the loss of freedom in dealing with patients, because that is familiar to all.

The present Bill to extend the National Health Insurance Scheme to persons earning £8 a week is the preliminary towards a State service. If medical attendance is to be provided for this class at twopence a week then a State Medical Service is near at hand. The bluffing and dictating adopted by the Ministry show that they have studied the methods of the Continental dictators and are following their technique closely. To yield to their demands or to seek appeasement will never be a successful policy, for experience has shown that appeasement always paves the way to further demands on the victim. The senior officials at the Ministry as well as the Minister should also be reminded that to introduce a major change into N.H.I. is a serious breach of faith in that a solemn pledge was given by a former Minister that there would be no major change in the N.H.I. service without previous consultation with the medical profession. It is also indefensible to make this vast and unnecessary extension when half the medical profession are engaged in the Services and unable to voice their views. In fact, it is reminiscent of similar methods now being adopted in New Zealand. The whole idea appears to be of political or departmental origin rather than the result of popular demand. At this decisive hour the profession must speak with a united voice and demand that this revolutionary extension of N.H.I. with all its implications be postponed until after the war.—I am, etc.,

Leeds, July 26.

J. H. E. MOORE.

SIR.—Those advocates of a State Medical Service who regard it as an escape from all their troubles are deluding themselves even if they do not delude those whom they wish to convert to their way of thinking. As T. E. Lawrence in the preface of the Oxford text of the *Seven Pillars of Wisdom* confessed when he cried aloud: "Those who dream by night explore the dusty recesses of their minds and wake in the morning to find that all is vanity; but the dreamers of the day are dangerous men, for they may act their dream with open eyes and make it possible," so we, who have dwelt so long in a world inhabited by those who deceived themselves that all was well when it was not, are not to be deceived by these dusty dreamers who pretend to hold the key which will open the door to a new heaven or a new earth. Like Dr. Primrose when he was in prison and found as his companion in distress the confidence trickster who had cheated him at the market, we seem to have heard all this before.

There is another note of warning from a very different quarter—namely, the preface to this year's edition of *Crockford*, which is applicable to medical circles equally with clerical affairs. The editor remarked: "Plans for a 'new order' are naturally being framed in Church circles. They do not seem to differ

much in principle from those that are being pursued elsewhere. The simple word 'loot' describes them all."

Finally, I would urge those who toy with the idea of the advantages to be gained by selling themselves to the State to ponder over the pages of *The New Despotism*, by Lord Hewart. I offer one quotation (p. 50):

"It may be said that there is no substantial ground for the fear of unfairness or corruption in the Civil Service. As to unfairness, people who have had disputes with public officials may sometimes conceivably hold a contrary opinion. As to corruption, that is a vice from which the service is completely and undoubtedly free. It is of vital importance that it should so continue. But if there were any great extension of the system of giving uncontrolled and arbitrary powers to public officials, it is as certain as that night follows day that corruption might creep in. We might then be cursed with the corrupt bureaucrat. The bureaucratic despot we already have. To take a simple instance, the treatment of the panel doctors under the National Health Insurance Acts is pure despotism. The doctors are liable, at the mere discretion of the official who acts for the Minister of Health, to be ruined professionally by being struck off the panel, or, as a lesser punishment, to be fined to an arbitrary extent. In one instance a fine of £1,000 was imposed on two doctors who carried on business in partnership. 'Excessive prescribing,' an offence wholly unknown to the law, which consists in prescribing for the patient medicines that are either too expensive in quality or too liberal in quantity, is one of the things for which a doctor may be penalized. One might think that, for a person who is bound by law to insure and pay contributions under the Acts, the best medicine ought to be prescribed in illness. But apparently that is not always the view of the department. One might wonder whether, in this matter, the interests of the patients are adequately taken into consideration."

—I am, etc.,

Heanor, Notts, July 29.

PHILIP TURTON, M.D., D.P.H.

SIR.—In the *Supplement* of August 2 (p. 16) Lieut.-Colonel S. H. Fairrie states that there is no example or precedent upon which to build or plan a State Medical Service except those of the Naval, Military, and Colonial Medical Services. Examples of partial State Medical Services do exist in various parts of the world—for instance, in Tasmania and the Western Highlands and the Hebrides. These schemes deal with scattered rural communities.

There also exists a complete, and apparently highly successful, State Medical Service dealing with both rural and urban communities in the U.S.S.R. In view of the excellent results obtained there, both in raising the level of health, as shown by vital statistics, and in increasing the number of medical personnel (from approximately 1 per 10,000 of the population in 1913 to approximately 1 per 1,000 to-day), I would suggest that the Medical Planning Commission would do well to study the organization of the State Medical Services of the U.S.S.R.—I am, etc.,

Brighton, Aug. 6.

R. S. SAXTON.

Medical Certificates

SIR.—In his letter (*Supplement*, July 19, p. 9) Dr. W. R. Somerset states: "In addition, in cases of workmen's compensation, workpeople are required to provide certificates to forward to insurance companies." I write to point out that this is not so; any such demand from an employer or his insurance company is illegal. Some twenty-five years ago, feeling it unreasonable that a man who has suffered an accident should be required to pay for a description of his injuries, I took legal opinion. I was advised that the Act forbade an injured person being put to that expense. Since then I have written no workmen's compensation certificates and my patients have received compensation when due. This has caused some trouble in persuading patients and in educating employers, who were invariably unacquainted with the law, but it has had its advantages in knowing one was not helping in a fraud those who keep us.

The opinion I had obtained was reported to the local Division, who decided it was no business of theirs, and resolved that the charge in future should be half a crown in place of the shilling previously charged. Without unduly trespassing on your space, may I point out that such a spirit is perhaps not unrelated to the unfortunate fact that when we want something for ourselves, as we do now in connexion with national health insurance, friends are somewhat lacking?—I am, etc.,

Grimsbury, July 26.

S. W. SWINDELLS.

Inadequacy of the Capitation Fee

SIR,—While there is complete unanimity among panel practitioners that the present capitation fee is inadequate and that all past advances have been too small, there is a great deal of confused thinking on the subject. It is generally agreed that the figure fixed in 1912 was too small, and it is commonly thought that changes in the cost of living since have created a complete disparity between the original figure and the figure as it stood in September, 1939, in relation to the cost of living. Much criticism has been levelled at the Insurance Acts Committee and at the British Medical Association itself in their handling of negotiations with the Minister of Health. When the Minister has stated that there were no grounds for an advance based on the rise in the cost of living his statement was greeted with frank incredulity by the average panel practitioner. The question of increased scope of service under our contracts is another matter, and I propose to deal with it later.

But let us examine the facts concerning the relationship between the capitation fee and the cost of living. Let it be understood at the beginning that the basic figures as published monthly in the Ministry of Labour *Gazette* are not directly applicable to the position. The figures for middle-class cost of living bear a relationship to the basic figures which must be on a sliding scale depending on the size of the income. Recent figures published by the British Medical Association gave the ratio to the basic rate as twelve to twenty-six—that is, the middle-class increase as about 46% of the monthly figure published. In February, 1920, when the basic rate was 130 (above 1914), the Civil Servants had advances in salaries which amounted to 91.5% at £200, 63.6% at £500, 55.6% at £800, and 54.3% at £1,000. These are equal respectively to 70%, 49%, 43%, and 42% of the basic rate, 130. If, therefore, for round figures we regard the middle-class cost-of-living figure to be 50% of the basic rate we shall not be far out.

In 1912 the capitation fee was fixed at 7s. with a "floating 6d." which might be devoted wholly or partly to dispensing costs. In practice the capitation fee averaged about 7s. 3d. In the table below this figure is used as a basis, and all advances are calculated as a percentage of it. The annual cost-of-living figures shown are the average of the monthly figures published in the Ministry of Labour *Gazette* from January, 1920, down to the present. No figures are available before 1920. The figures shown are percentage advances on the 1914 basic figure. The last column shows the appropriate capitation fee had the cost-of-living figures for the middle classes been closely followed.

Year	Yearly Average of Monthly Cost-of- living Index	Middle-class Index 50% Basic Rate	Actual Capitation Fee	% Inc. Rise on 7s. 3d. 1912 Rate	Approp. Fee to Cost of Living
1920	148.75	74	11/-	52	12/7
1921	125.8	63	11/-	52	11/10
1922	82.58	41	9/6	31	10/3
1923	73.65	37	9/6	31	9/11
1924	74.75	37	9/-	24	9/11
1925	75.58	38	9/-	24	10/-
1926	72.25	36	9/-	24	9/10
1927	67.5	34	9/-	24	9/8
1928	65.6	33	9/-	24	9/7
1929	64.0	32	9/-	24	9/4
1930	57.8	29	9/-	24	9/-
1931	47.5	24	8/1.2	12	8/10
1932	43.8	22	8/1.2	12	8/8
1933	39.75	20	8/1.2	18	8/9
1934	41.2	21	8/6.6	18	8/9
1935	42.66	21	9/-	24	8/11
1936	46.75	23	9/-	24	9/2
1937	54.25	27	9/-	24	9/3
1938	56.25	28	9/-	24	9/4
1939	57.9	29	9/-	24	10/4
1940	83.75	42	9/-	24	10/10
1941 (1st half)	98.0	49	9/-	24	

It will be seen that in the years 1930-9 claims for increase in the capitation fee based on increase in the cost of living could not be justified. A case might have been made out in the previous decade, but the cost-of-living index was falling gradually to meet the panel fee, which nevertheless always lagged an appreciable distance behind. In point of fact, relatively the worst year was 1920, when Lord Addison, then Minister of Health, who has been commended by your correspondent Dr. Burges in your issue of August 2, awarded a panel fee of 11s.

The appropriate figure was 12s. 6d. The capitation fee remained at 7s. 3d. throughout the 1914-18 war, though the cost of living must have risen steeply. In 1918 and again in 1919 percentage increases were given, which were limited in scope and depended on the total net income earned. In our recent application for an advance the Minister has stated that only the lowest-paid groups have so far been given a wartime advance based on rises in the cost of living.

Every panel practitioner who has been in practice for fifteen years or over will appreciate that there has been an enlargement in the scope of work required under our contract. How large this is will be shown when the opportunity comes to present the case prepared by the Insurance Acts Committee to the Minister of Health. What we must not forget is that the original figure to which we have been tied was too low, and that increased services have made its inadequacy more marked; that much that is weak—and there are weaknesses—in the panel system arises from too low a capitation fee coupled with a relatively too high permitted maximum number of insured patients.

When the whole question is reopened with the Minister of Health our aim should be to establish a capitation fee based on the middle-class cost-of-living index (50% of the basic index), and with 10s. taken as the appropriate figure on which to calculate the increase. Calculated thus the appropriate rate for 1939 would have been 13s. and for 1941 15s. If this basis was established it should be possible, and would be eminently desirable, to reduce the permitted maximum number from 2,500 to 2,000. If dependants were brought into the scope of the national health insurance on the same basis, then a total of about 3,500 would be the appropriate maximum. Thus, our aim in striving for an adequate capitation fee should be not merely to obtain a bigger average income for the panel practitioner but also to improve the medical services and increase the time devoted to each individual panel patient.—I am, etc.,

F. M. ROSE,

Hon. Sec., Preston Division, British Medical Association and Preston Panel Committee.

Aug. 8.

BRITISH MEDICAL ASSOCIATION

ANNUAL GENERAL MEETING

Notice is hereby given that the Annual General Meeting of the British Medical Association will be held in the Great Hall, British Medical Association House, on Thursday, September 11, at 12.30 p.m.

Business

1. Minutes of meeting held on October 28, 1940.
2. Appointment of Auditors.
3. Any other business.

G. C. ANDERSON,
Secretary.

Diary of Central Meetings

SEPTEMBER

- 11 Thurs. Executive Committee, 10 a.m.
Council, 11 a.m.
Special Meeting of Representatives of Home Divisions,
12 noon (continuing on following day).

Branch and Division Meetings to be Held

EDINBURGH AND SOUTH-EAST OF SCOTLAND BRANCH: SOUTH-EASTERN COUNTIES DIVISION.—At Royal Hotel, Galashiels, Sunday, August 24, 3 p.m. Agenda: Annual Report of Council; Meeting of Representatives in September; Medical Planning Commission; Report of meeting of Panel Committees' Representatives, etc.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION,
1, Wimpole Street, W.—*Colindale Hospital*, Thurs., F.R.C.S.
(Final) Course in Urology.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced: (1) Clyde, Kildonan, and Loth., (2) Golspie and Rogart, (3) Lairg (Sutherlandshire), and (4) Sandwich (Kent). Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by August 19.

APPOINTMENTS

LINDSAY, James, M.D., Examining Factory Surgeon for the Royton District (Lancashire).

MEDICAL WAR RELIEF FUND

TWENTIETH LIST

Previously acknowledged £29,690 12s. 2d. and £100 3½%
Conversion Stock and £40 3% Defence Bonds

Individual Subscriptions

- £25.—S. D. M.

Boyd £2 2s.; Mr. J. T. Chesterman £2 2s.; Dr. J. L. J. McCormick £2 2s.; Dr. T. F. Murphy £2 2s.; Dr. W. J. Clancy £1 1s.; Dr. E. C. Eaves £1 1s.

£12 9s.—Practitioners in the North Middlesex Division—per Dr. J. R. Richmond Ritchie (amount already sent £166 3s.); Dr. D. Evans £2 2s.; Dr. W. R. B. Dickinson £2 2s.; Mr. I. Lewis £1 1s.; Dr. W. G. Richards £3; Dr. H. H. Schafer £1 1s.; Dr. J. A. P. Scott £3 3s.

£8 8s.—Practitioners in Scunthorpe Division—per Dr. J. R. Baker (amount already sent £59 6s.); Dr. A. M. Macgregor £3 3s.; Mr. W. H. Bailey £5 5s.

£6 6s.—Per Dr. J. M. Johnstone, N. Staffs L.M.W.C. (amount already sent £791 8s.); Dr. R. M. Barrow £5 5s. (2nd donation); Dr. H. B. Binks £1 1s.

£6.—Practitioners in Reigate Division—per Dr. L. J. Barford (amount already sent £143 16s.); Dr. B. J. F. Jackson-Taylor £3; Dr. S. Morton Mackenzie £3.

£5 5s.—Northamptonshire Medical Charity—per Dr. D. G. Greenfield (amount already sent £478 11s. 6d.); Dr. W. M. Robson; Practitioners in the Bolton Division—per Dr. H. W. Bowyer (amount already sent £67 16s.); Dr. B. Thornley; Practitioners in the Shropshire and Mid-Wales Branch area—per Dr. G. Mackie (amount already sent £195 7s.); Dr. A. E. Nicholls.

£2 2s.—Practitioners in the area of the Marylebone Division—per Mr. F. MacG. Loughnane (amount already sent £107 5s.); Dr. Agnes Savill.

£1 1s.—Practitioners in Buckinghamshire—per Dr. R. W. McConnel (amount already sent £288 12s.); Dr. H. C. Woodhouse.

Local Medical and Panel Committees

£105.—Cheshire.

£19 16s. 4d.—Dumbarton (2nd donation).

The following donations have come in since the above was set in type:

Individual Subscriptions

- £10.—"Leicester."
£5 5s.—Dr. C. P. Miller, Cheam; Dr. F. R. Sturridge, London.
£2 2s.—F/O A. M. Ferens Batty, R.A.F.V.R.; Dr. S. A. B. Black, Nigeria; Dr. N. F. Lawers, Bideford.
£1 1s.—Dr. H. Stedman, Bushey Heath.
10s. 6d.—Dr. T. Benson Evans, Prestatyn (5th donation).
£352 3s.—Practitioners in the Swansea area—per Drs. T. Ben Thomas and T. W. Davies; Dr. E. W. M. H. Phillips £7 7s.; Dr. T. M. Anderson £5 5s.; Dr. E. D. Owen £5 5s.; Drs. M. and H. V. Davies, £5 5s.; Dr. A. F. S. Sladden £5 5s.; Dr. H. R. Frederick £5 5s.; Dr. U. Marks £5 5s.; Dr. T. J. Evans £5 5s.; Mrs. E. K. R. Thomas £5 5s.; Mr. H. W. Gabe £5 5s.; Colonel C. L. Isaac £5 5s.; Mr. C. P. Robinson £5 5s.; Drs. D. Rees and R. J. Isaac £5 5s.; Dr. J. Bowen-Jones £5 5s.; Dr. W. W. Hellyer £5 5s.; Mr. J. Crowther £5 5s.; Dr. W. E. Rees £5 5s.; Dr. I. Jones £5 5s.; Dr. H. J. Davies £5 5s.; Dr. J. L. Davies £5 5s.; Dr. I. Davies £5 5s.; Mr. H. E. Quick £5 5s.; Dr. C. Davies £5 5s.; Dr. T. W. David £5 5s.; Mr. W. J. Richards £5 5s.; Dr. D. H. Isaac £5 5s.; Dr. T. Imrie £5 5s.; Mr. W. F. Brook £5 5s.; Dr. R. P. Jones £4 4s.; Dr. J. Williamson £3 3s.; Mr. W. H. O. Woods £3 3s.; Dr. J. L. Jones £3 3s.; Dr. P. O. Davies £3 3s.; Dr. T. J. Hargest £3 3s.; Dr. R. D. Lewis £3 3s.; Dr. H. Owen £3 3s.; Dr. D. B. Harrington £3 3s.; Dr. W. MacLennan £3 3s.; Dr. L. Watkins £3 3s.; Dr. T. G. Jenkins £3 3s.; Dr. A. J. Amor £3 3s.; Dr. J. Kyle, £3 3s.; Drs. L. F. Marks and Parker £3 3s.; Dr. W. H. Thomas £3 3s.; Dr. M. Goldberg £3 3s.; Dr. W. H. Jones £3 3s.; Mr. W. Maclean £3 3s.; Dr. L. W. Heflerman £3 3s.; Dr. C. G. Gooding £3 3s.; Dr. M. Owen £3 3s.; Dr. W. Taylor £3 3s.; Dr. J. Shikbo £3 3s.; Dr. P. J. Ryan £3 3s.; Dr. F. M. L. George £3 3s.; Dr. T. McClure £3 3s.; Dr. F. G. Thomas £3 3s.; Dr. F. M. L. Jones £3 3s.; Dr. D. J. Hughes £2 2s.; Dr. R. J. Isaac £2 2s.; Dr. J. Lloyd £2 2s.; Dr. F. H. K. Knight £2 2s.; Dr. T. W. Davies £2 2s.; Dr. F. G. Jones £2 2s.; Dr. F. B. Thomas £2 2s.; Dr. I. O. Martin £2 2s.; Dr. S. I. Williams £2 2s.; Dr. G. A. Madel £2 2s.; Dr. J. D. Robertson £2 2s.; Dr. W. V. Howells £2 2s.; Dr. C. James £2 2s.; Dr. J. W. F. Jones £2 2s.; Dr. T. Davies £2 2s.; Dr. N. N. Moulson £2 2s.; Dr. J. A. Noot £2 2s.; Dr. H. S. Davies £2 2s.; Dr. J. Evans £2 2s.; Dr. D. Hughes £2 2s.; Dr. I. P. G. Howells £2 2s.; Dr. R. J. Smith £2 2s.; Dr. S. Gordon £2 2s.; Dr. H. W. Howell £2 2s.; Dr. D. B. Phillips £2 2s.; Dr. W. E. Thomas £2 2s.; Dr. M. H. MacLaine £2 2s.; Dr. H. E. James £2 2s.; Dr. C. E. Kimister £2 2s.; Dr. T. J. Walters £2 2s.; Dr. E. Aslett £2 2s.; Dr. D. Davies £2 2s.; Dr. J. M. Morris £2 2s.; Dr. J. Lloyd £2 2s.; Dr. S. A. Gailley £2 2s.; Dr. G. Jones £2 2s.; Dr. H. Peters £2 2s.; Dr. R. Jamieson £2 2s.; Dr. T. D. Llewellyn £2 2s.; Dr. J. C. Drury £1 1s.; Dr. M. T. Rutchings £1 1s.; Dr. F. Kellerman £1 1s.; Dr. G. M. Evans £1 1s.; Dr. A. Staples £1 1s.; Dr. M. Williams £1 1s.; Dr. G. Evans £1 1s.; Dr. G. J. Frazer £1 1s.; Dr. A. Evans £1 1s.; Dr. R. Edwards £1 1s.; Dr. J. Kerr £1 1s.; Dr. N. Evans £1 1s.; Mr. M. J. Powell £1 1s.; Dr. G. H. Garfield £1 1s.; Dr. G. Ellis £1 1s.; Dr. A. E. M. Herbert £1 1s.; Dr. G. A. Stephens £1 1s.; Dr. M. Brighton £1 1s.; Dr. T. H. Davies £1 1s.; Dr. E. R. Porter £1 1s.; Dr. H. R. Tighe £1 1s.; Dr. S. McClure £3 3s.; Dr. T. C. Mott £2 2s.; Dr. E. Coyne £2 2s.; Dr. P. Jones £1 1s.

£293 5s. 11d.—Malaya Branch.

£37 3s. 9d.—Hong Kong and South China Branch.

£33 10s.—Practitioners in the area of the Cardiff Division—per Dr. F. Y. Pearson (amount already sent £371 3s.); Dr. C. A. Probert £2 2s.; Dr. N. L. Probert £2 2s.; Dr. F. L. Sessions £1 1s.; Dr. W. D. Lovelock-Jones £2; Dr. J. G. Wilson £1 1s.; Dr. T. J. Hennelly £3 3s.; Dr. I. I. Thomas £1 1s.; Dr. J. J. Ashby £10 10s.; Mr. D. Ioan-Jones £10 10s.

£26 16s.—Practitioners in Exeter Division—per Dr. J. D. R. Murray and Dr. N. Y. Paget (amount already sent £186 5s. 6d.); Mr. H. Andrew (2nd donation). Dr. J. Kingdon Frost, Dr. M. Kaye, Dr. D. J. L. Routh, Dr. R. Shove.

£19 19s.—Practitioners in area of Belfast Division—per Dr. S. R. Hunter (amount already sent £347 19s.); Mr. R. J. McConnell £5 5s.; Dr. G. Hamilton £5 5s.; Dr. D. C. Lennie £3 3s.; Dr. H. Wilson £2 2s.; Dr. W. Rutherford £2 2s.; Dr. W. H. Hood £2 2s.

£15 5s.—Croydon Division—per Dr. S. A. Forbes (amount already sent £150 15s.); Dr. W. V. Braddon £5; Mr. V. Wilkinson £2 2s.; Dr. C. I. Stockley £5; Dr. J. Newton Hudson £3 3s.

£11 11s.—Glasgow Division—per Dr. Inglis Cameron (amount already sent £374 3s.); Dr. G. Young £5 5s.; Drs. R. Black and D. McFarlane £5 5s.; Dr. A. S. Barr £1 1s.

£1.—Practitioners in area of East Norfolk Division—per Dr. J. A. Eddy (amount already sent £83 9s.); Dr. C. H. W. Page.

The contributors to the £88 11s. from the Darlington Division were as follows: Dr. J. M. Ross £5 5s.; Dr. D. Stubbs £5 5s.; Dr. J. M. Scott £5; Dr. T. L. Wormald £3 3s.; Dr. C. J. Kirk £2 2s.; Dr. E. A. Hughes £2 2s.; Dr. H. C. Pearson £2 2s.; Dr. C. D. Wilson £2 2s.; Dr. W. C. Fothergill £2 2s.; Dr. R. A. Adamson £2 2s.; Dr. D. Stone £2 2s.; Dr. W. G. Annan £2 2s.; Dr. W. A. Jaques £2 2s.; Dr. W. G. White £2 2s.; Dr. W. Meikle £2 2s.; Dr. J. Sinclair £2 2s.; Dr. A. D. Smith £2 2s.; Dr. M. Archdale £2 2s.; Dr. W. Pickles £2 2s.; Dr. A. Morrison £2 2s.; Dr. F. C. Pridham £2 2s.; Dr. D. Todd £2 2s.; Dr. Peill £1 10s.; Dr. J. Strachan £1 1s.; Dr. I. Brown £1 1s.; Dr. J. Higgins £1 1s.; Dr. K. Girgis £1 1s.; Dr. B. Freshwater £1 1s.; Dr. R. Leishman £1 1s.; Dr. P. W. C. Speirs £1 1s.; Dr. E. R. Dingle £1 1s.; Dr. A. Ingham £1 1s.; Dr. R. P. Rosser £1 1s.; Dr. G. A. Dawson £1 1s.; Dr. D. V. Haigh £1 1s.; Dr. C. B. Whitehead £1; Dr. P. A. M. Macgregor £10s. 6d.; Dr. J. Blair £10s. 6d.; Dr. B. Dawson £10s. 6d.; Major J. H. Graham £10s.; Anonymous £15 1s. 6d.

Local Medical and Panel Committees

£20.—Bury.

Total—£31,625 17s. 5d. and £100 3½% Conversion Stock and £40 3% Defence Bonds

Correction: The donation of £5 credited to Dr. J. G. Wardrop in the Nineteenth List under Warwick and Leamington and Rugby Divisions should have been credited to Dr. D. Wardrop.

It will be noticed that there is an anonymous contribution of £21. This came in the form of a Warrant as a "token payment in recognition of services to a member of my family" by three members of the medical profession in a rural area, whose names are mentioned in the note, which has apparently come from a lay person. The profession will appreciate not only the generous contribution made to the Fund but also the spirit which prompted the gift. This is the only means we have of acknowledging the contribution.

Correspondence

Capitation Fee

SIR.—I regret that the number of motions, the numerous speakers, and the course of the debate prevented me putting before the Conference of Delegates of Panel Committees a point which I had previously put to the West Riding Panel Committee. May I, Sir, through your kindness give it a belated but wider publicity?

At the moment the Government pays into a "pool," from which certain charges have to be met, the sum of 13s. From this the profession receives 9s.—that is, nine-thirteenths. It is proposed in the new Bill to pay into that pool the sum of 14s. 6d., for which sum 9s. 9d. will be paid to the profession. Now nine-thirteenths of 14s. 6d. comes to, roughly, 10.03s., which is rather more than 9s. 9d. So that the apparent increase of 9d. per head in the capitation fee is in reality a reduction in the proportion received by the profession from the "pool." In the district from which I come that is known as the "Irishman's rise."

It may be said that the 9d. is in fact all that can be obtained from the "pool." Against this is the fact that on June 30 a deputation from the I.A.C. (see their report) were told by the Minister "that according to present calculations there would not be sufficient money in the pool to pay the doctors a capitation fee of more than 9s. 6d." At that date the new Bill had not been suggested, so the "present calculation" must refer to a pool filled only with 13s. Observe, therefore, Sir, that it is possible to pay 9s. 6d. out of 13s. and only 9s. 9d. out of 14s. 6d.: the "Irishman's rise" more than ever.

It is a good rule that he who criticizes should have some constructive suggestions to make. I have two—the one radical, the other palliative. The only radical cure, so far as I can see, is a State Medical Service. If we must be slaves, better be slaves of the State than of the approved societies. The palliative cure is well described in that Book which formed the earliest reading for most of us and will, I hope, be the ultimate consideration of all of us. Therein, Sir, we find that the poor widow seeking justice found it with the help of neither logic nor evidence but simply by continuous pleading. We are none of us without some influence. Let us, I suggest, rather than rock the boat, quarrel with the rowers, or debate the exact point on which we shall land, join wholeheartedly together to make for land; in season and out of season present a united front and a united complaint, and mass in our favour that public opinion which has been and is the ultimate court of appeal in our country.—I am, etc.,

Yedra, Aug. 6.

JAMES E. OUTHWAITE.

State Medical Service

SIR.—Readers of Lieut-Colonel S. H. Fairrie's letter (*Supplement*, August 2, p. 16) will have noticed that: (1) he concludes that the "idea of a State Medical Service . . . originated from within the ranks of the medical profession"; (2) he assumes that, as a result of the war, this country must of necessity enter a period of extreme financial stringency. In my opinion he has not proved his conclusion, and his assumption is without foundation.

In the first instance no consideration appears to have been even to the possible part played in the matter by the doctrinaire politician. Few of us would like to see medical policy made the playing of party politics, but we must not for this reason allow ourselves to be blinded to the fact that party politics are already established in our midst. It may not be generally known, but it is nevertheless a fact, that there is in existence an association, with many national and international non-medical affiliations, whose primary object is "to work for a Socialized Medical Service." (I take it that "socialized" in this connexion is synonymous for "national" or "State.") Membership of the association is open to individuals included in one or more of seven categories provided they accept a particular political theory. The first category is "Registered or Qualified Medical Practitioners." I have in my possession documentary evidence which proves that propaganda in favour of a State Medical Service emanates from this association. Though I cannot say where the "idea of a State Medical Service originated," I am convinced that it was not within the ranks of the medical profession.

The assumption relating to finance is based on the almost universal delusion that a great war must of necessity be followed by a period of extreme financial difficulty. The fact is that great wars are usually followed by poverty and distress, but the nature of things does not make this sequence inevitable. If we allow it to happen again we shall only get what we deserve by failing to take the sane and feasible steps by which it can be avoided. It can easily be proved then (though there is not space to do it now) that an ever-increasing wealth of goods and services can be made available for distribution among the people of this country when the war comes to an end. There are two practicable methods by which this distribution can be made: (a) By means of a central planning authority which will decide, on the best authority of course, what is best for the people and will make distribution on those principles. "The standard of living" as compared with the present level would probably be high, but individual initiative and freedom of choice among the mass of the people would be reduced to a minimum. Among other things an adequate supply of standardized doctors (duly certified by the proper authority) would be distributed to a standardized people. So much for the authoritarian way. (b) The introduction of the second method would necessitate the making of certain simple adjustments in our money system. These are not of a kind which would lead to the impoverishment of any section of the community. Their chief side-issue would be to take irresponsible power out of the hands of small groups which now hold it. This threat to power maniacs is perfectly appreciated by them, and here is to be found the explanation of the colossal opposition which any suggestion for sane money reform calls forth. Once this opposition were overcome the financial adjustments necessary for the satisfactory distribution of goods and services could be put into practice without the least difficulty. If this method were adopted "freedom of choice" would extend very far beyond the bounds in which Mr. Brown is free to call in Dr. Jones or Dr. Smith.—I am, etc.,

Bexley, Kent, Aug. 4.

E. U. MACWILLIAM.

Domiciliary Visits of Public Vaccinators

SIR.—With regard to the correspondence on vaccination, the following series (not a heavy list) of last week's vaccination visits, fifteen in all, speak for themselves. (1) Vaccinated. (2) Out. (3) Vaccinated. (4) Postponed (conjunctivitis). (5) House unoccupied (mother gone to hospital, I am informed). (6) Vaccinated. (7) Vaccinated. (8) Vaccinated. (9) No reply (presumably "out"). (10) Vaccinated. (11) Out (left message to say "refusing" in any case). (12) Vaccinated. (13) Refused (no previous warning to that effect). (14) Out. (15) Refused (no previous warning to that effect).

It can be seen that eight visits (over 50%) have been futile. Those who refused have apparently not even troubled to sign the "conscientious clause," nor to warn the vaccination officer. It would appear that an immense amount of time and petrol could be saved if the vaccinator could attend a central clinic. Could he not attend for that purpose the infant welfare clinics for a short period while they are in session?—I am, etc.,

Smethwick, Aug. 2.

JAMES SHAW.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

Surgeon Lieut.-Commander D. W. Pratt (Emergency) has been transferred to the Permanent List.

Acting Surgeon Lieut.-Commander J. Whittington to be Surgeon Lieutenant-Commander.

Surgeon Lieuts. W. H. C. Watson and J. M. Fitzpatrick to be Surgeon Lieutenant-Commanders.

ROYAL NAVAL VOLUNTEER RESERVE

Acting Surgeon Lieut.-Commander R. A. Mozz to be Surgeon Lieutenant-Commander.

Probationary Temporary Surgeons Lieuts. J. P. F. Hummel, F. P. S. Malone-Barrett, R. A. H. Simpson, D. McLean, C. Halamander, G. R. Waterman, T. T. Davies, M. B. D. Welland, and C. H. Edwards to be Temporary Surgeon Lieutenants.

ARMY

Lieut.-General Sir William P. MacArthur, K.C.B., D.S.O., O.B.E., late R.A.M.C., has retired on retired pay.

Major-General R. W. D. Leslie, C.B., O.B.E., K.H.P., late R.A.M.C., has retired on retired pay.

Colonel A. Hood, C.B.E., late R.A.M.C., to be Lieut.-General.
Colonel (acting Major-General) P. S. Tomlinson, D.S.O., late R.A.M.C., to be Major-General.
Colonel (temporary Brigadier) C. M. Finny, O.B.E., K.H.S., late R.A.M.C., to be acting Major-General.
Lieut.-Colonels J. W. C. Stubbs, D.S.O., M.C., from R.A.M.C., and H. G. Winter, M.C., from R.A.M.C., to be Colonels.

ROYAL ARMY MEDICAL CORPS

Colonel T. S. Dudding, O.B.E., retired pay, late R.A.M.C., has reverted to the rank of Major at his own request whilst employed during the present emergency.
Lieut.-Colonel (temporary Colonel) J. G. Ronaldson, M.C., having attained the age for retirement, has retired, and remains employed.
Lieut.-Colonel H. V. Stanley, M.B.E., M.C., retired pay, has reverted to the rank of Major at his own request whilst employed during the present emergency.
Majors (temporary Lieut.-Colonels) W. Russell, M.C., and L. A. J. Graham to be Lieutenant-Colonels.
Major G. S. Douglas to be Lieutenant-Colonel.
Major R. T. Cox has retired on retired pay.
Captain C. E. Watson has retired, receiving a gratuity. (Substituted for the notification in the *London Gazette* of May 27, 1941.)
War Substantive Captain A. J. Ireland has resigned his commission.
Lieut. J. F. F. Garry has relinquished his commission on account of ill-health.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major W. R. O'Farrell, having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers.

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS
War Substantive Captain F. A. Gaydon has ceased to belong to the Supplementary Reserve of Officers on account of ill-health.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major W. A. Mackey, from supernumerary for service with the Medical Unit, Glasgow University Contingent, Senior Division, O.T.C., to be Major.
War Substantive Captains R. O. Barber and P. Wade have relinquished their commissions on account of ill-health.

Second Lieut. (War Substantive Lieut.) J. D. F. Norman, from Royal Artillery, Territorial Army, to be Lieutenant.

The notifications regarding transfer of the following officers from Territorial Army Reserve of Officers in the *London Gazette*, the dates of which are indicated in parentheses, have been cancelled: Captains (now Temporary Majors) G. N. Bailey and D. R. Hood, Captains R. Woodside and G. T. Pitts, and Lieut. (now War Substantive Captain, Temporary Major) J. A. Kerr (September 13, 1939); Major (now Temporary Lieut.-Colonel) A. O. Bekken, O.B.E., Captains (now Temporary Majors) K. M. Morris, E. F. S. Morrison, and S. C. Swinburne, and Captains D. M. Mackenzie, T. H. Sansome, J. Kerr, J. H. B. Livingston, and J. O'Donnell (September 14, 1939); Lieut. (now War Substantive Captain) C. Stewart (September 22, 1939); Majors W. Brockbank and L. F. E. Jeffcoat (September 23, 1939); Lieut.-Colonel T. E. A. Carr, Majors (now Temporary Lieut.-Colonels) W. Barclay, M.C., and J. L. Menzies, M.C., Majors C. W. Greenhill and E. T. H. Lea, and Captains (now Temporary Majors) F. J. Whitclaw and H. P. Gabb, M.C. (September 26, 1939); Majors (now Temporary Lieut.-Colonels) S. S. Greaves, D.S.O., M.C., and A. M. Hughes, M.C., Major H. H. Fowler, and Captain (now Temporary Major) F. Evans, M.B.E. (September 30, 1939); Captain (now Temporary Major) G. Chesney and Lieut. (now War Substantive Captain) B. McK. Dick (October 3, 1939); Major (now Temporary Lieut.-Colonel) N. H. H. Haskins, M.C., Majors J. F. Fraser and H. Wilson, M.C., Captain (now War Substantive Major, Temporary Lieut.-Colonel) J. F. Ward, Captains (now Temporary Majors) M. E. D. Roberts and A. C. Sinclair, and Lieuts. (now War Substantive Captains, Temporary Majors) M. J. Bett and E. T. Colville (October 6, 1939); Lieut.-Colonels J. O. Thomas and J. S. M. Connell, Majors (now Temporary Lieut.-Colonels) G. V. Davies and J. G. Graham, Majors R. W. Fairbrother, A. M. Jones, and H. L. Sheehan, Captains (now Temporary Majors) C. E. Sykes, H. G. Dodd, and F. A. Smorfit, and Captains J. G. Morrin, A. W. Uloth, and A. N. Smith (October 10, 1939); Majors H. M. McE. Morris and F. H. Scotson (October 13, 1939); Major F. D. Marsh, M.C. (October 17, 1939); Major (now Temporary Lieut.-Colonel) C. B. Levick and Major A. C. M. Savage, T.D. (October 20, 1939); Captain (now Temporary Lieut.-Colonel) H. S. Allen (October 27, 1939); Lieut.-Colonel A. A. Eaggar, C.B.E. (November 1, 1939); Lieut.-Colonel (now Major) W. Bowater, M.C. (November 3, 1939); Captain (now Temporary Major) C. S. Swinburne, Captain D. E. Denny-Brown, and Lieut. (now War Substantive Captain) C. A. Croman (November 6, 1939); Lieut.-Colonels J. A. Stenhouse, T.D., and H. V. Walsh, T.D., Majors (now Temporary Lieut.-Colonels) H. Foxton, M.C., and G. M. Heiron, Major C. J. Fox, and Captains (now Temporary Majors) H. B. Dodwell and R. E. Davie, M.C. (November 8, 1939); Major (now Temporary Lieut.-Colonel) G. W. Wigg, T.D., and Captain (now Temporary Major) H. G. Neill (November 15, 1939); Major H. J. Heathcote (November 17, 1939); and Captain (now Temporary Major) F. W. Bury (December 8, 1939).

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS
Captain S. Summerson, having attained the age limit, has relinquished his commission and retains his rank.

LAND FORCES: EMERGENCY COMMISSION

ROYAL ARMY MEDICAL CORPS

War Substantive Captains A. C. Jepson, A. B. Monk, and G. G. Michell have relinquished their commissions on account of ill-health.

The surnames of Lieuts. H. W. Cowen, B. S. Tulloch, and St. J. C. B. Serjeant are as now described and not as stated in *Supplements to the London Gazette* dated November 15, 1939, March 5, 1940, and February 7, 1941, respectively.

Lieut. R. A. Coughlan to take rank and precedence in his Corps and in the Army as if his appointment bore date May 14, 1941.

The initials of Lieut. A. J. M. Drennan are as now described and not as stated in a *Supplement to the London Gazette* dated June 6.

To be Lieutenants: C. I. N. Morgan, A. N. Barker, R. Bloom, A. G. C. Cox, T. J. Eason, F. A. Frank, P. H. Garrard, T. Gass, C. G. Gordon-Wilson, J. S. Lilligrap, W. C. Maughan, S. M. Pruss, A. I. Ross, R. Sherrard, G. A. Simpson, J. W. Alden, J. N. Alexander, A. S. Burns, A. B. Cornick, J. A. MacDonald, H. R. Duval, G. P. Holderness, A. W. P. Johnson, G. B. Libbey, J. MacDonald, R. B. McMartin, A. Mack, W. C. Muir, B. A. Protheroe, T. W. L. Roberts, J. D. Robertson, D. L. Shaw, F. Shaw, L. Solomon, R. Steen, C. D. Stewart, W. F. J. Weston, J. L. Washington, D. J. Burgess, A. The notification regarding Lieut. A. B. Cowley in the *Supplement to the London Gazette* dated June 27, 1941, is cancelled.
Dr. (Lieut.) J. R. M. Johnson has relinquished her appointments.

BRITISH MEDICAL ASSOCIATION

ANNUAL GENERAL MEETING

Notice is hereby given that the Annual General Meeting of the British Medical Association will be held in the Great Hall, British Medical Association House, on Thursday, September 11, at 12.30 p.m.

Business

1. Minutes of meeting held on October 28, 1940.
2. Appointment of Auditors.
3. To receive and approve the statement of accounts of the Association as published in the *Supplement to the British Medical Journal* of May 17, 1941.
4. Any other business.

G. C. ANDERSON,

Secretary.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following M.R.C.P. courses: (1) neurology at West End Hospital for Nervous Diseases, August 26 to September 19, Tuesdays and Fridays, at 3.30 p.m.; (2) heart diseases at Royal Chest Hospital, August 27 to September 17, Wednesdays, at 3.30 p.m.; (3) chest and heart diseases at London Chest Hospital, September 2 to 25, Tuesdays and Thursdays, at 2 p.m. Also the following Final F.R.C.S. courses: (1) clinical course at St. Mary Islington Hospital, September 3 to 24, Wednesdays, at 2 p.m.; (2) clinical orthopaedics at Royal National Orthopaedic Hospital, Stanmore, September 6 to 27, Saturdays, at 2.15 p.m.; (3) comprehensive course at Royal Cancer Hospital, every morning, September 29 to October 17.

The Fellowship of Medicine announces the following postgraduate courses for Final F.R.C.S. candidates: clinical course at St. Mary Islington Hospital on Wednesdays at 2 p.m., from September 3 to 24; clinical orthopaedic course at the Royal National Orthopaedic Hospital on Saturdays at 2.15 p.m., from September 6 to 27; comprehensive revision course, every morning at 10 a.m., from September 29 to October 17.

A series of lectures on "War Surgery of the Extremities" will be given at the British Postgraduate Medical School from Monday to Friday, September 1 to 5 (both days inclusive), beginning at 10 a.m. daily. The fee for the course is £1 1s. Officers of the armed Forces and whole-time officers of the E.M.S. will be admitted free provided they have obtained necessary leave and registered their names before the commencement of the course. Applications for admission should be addressed to the Dean of the British Postgraduate Medical School, Ducane Road, W. Further war surgery courses will be held as follows: beginning Monday, September 15, "War Surgery of the Abdomen"; beginning Monday, September 29, "War Medicine."

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*West End Hospital for Nervous Diseases*: Tues. and Fri., 3.30 p.m., M.R.C.P. Course in Neurology. *Royal Chest Hospital*, City Road, E.C.: Wed., 3.30 p.m., M.R.C.P. Course in Heart Diseases. *Brompton Hospital*, S.W.: Mon. and Thurs., 5 p.m., M.R.C.P. Course in Chest Diseases. *Colindale Hospital*, The Hyde, N.W.: Thurs., F.R.C.S. (Final) Course in Urology.

VACANCIES

EXAMINING FACTORY SURGEONS.—The appointment at Uddington (Lancaster) is vacant. Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by August 26.

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced: Maiden Newton (Dorsetshire); Alyth (Perthshire). Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by September 2.

APPOINTMENTS

HEATHER, J. C., M.D., B.S., M.R.C.S., L.R.C.P., Examining Factory Surgeon for the Coventry East District (Warwickshire).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post, Monday morning to ensure insertion in the current issue.

BIRTH

FORREST-HAY.—On August 8, at "The Riddings," Bewdley, Worcestershire, to Marjorie, wife of Captain Graham Forrest-Hay, R.A.M.C., W.S., a son. Both well.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 30 1941

RECENT B.M.A. ACTIVITIES

In the absence of a Supplementary Report of Council, members of the Association will be glad of a brief report on a number of points dealt with by the Association in recent months.

Protection of Practices Schemes

A. POSITION IN RELATION TO THE GOVERNMENT'S INTENTION TO INCLUDE WITHIN THE SCOPE OF NATIONAL HEALTH INSURANCE NON-MANUAL WORKERS WITH INCOMES UP TO £420 PER ANNUM

Committees administering Protection of Practices Schemes are being advised to give effect to the following recommendations after consultation with the clerk to the insurance committee for the area:

1. That where any new entrant to national health insurance (including the group brought into N.H.I. under the new legislation) applies to be placed on the list of an acting practitioner, it is the duty of that practitioner to ascertain the name of the practitioner formerly or normally consulted by the patient, and if that doctor is an absentee the acting practitioner may accept the patient only on behalf of the absentee. The patient would thus become a "temporary acceptance" on the acting practitioner's list, and if the name of the absentee is included in the list of the insurance committee for the area the fees for treatment would be distributed in accordance with the local scheme.

2. In order that non-insurance absentee practitioners may become entitled to the moneys for the treatment of those non-private patients who are new entrants to N.H.I., Local Medical War Committees should urge the legal personal representatives of the absentees to make application for the inclusion of the absentees' names in the list of the insurance committee for the area as from January 1, 1942.

B. EXTENSION OF PROTECTION OF PRACTICES SCHEMES

Committees administering these schemes have been asked to consider the adoption of a supplementary agreement which would afford protection under the terms of the local agreement to an acting practitioner who is killed or dies, who is permanently or temporarily incapacitated from performing the duties of his profession, or who, in consequence of damage or destruction of professional premises by enemy action, is temporarily unable to perform the duties of his profession. A model supplementary agreement has been supplied.

C. OBSERVANCE OF PROTECTION OF PRACTICE AGREEMENTS

The Council informed local committees administering the Protection of Practices Schemes that it was prepared, in a limited number of cases which were supported by the necessary evidence, to assume financial responsibility for the legal action necessary to enforce observance of the protection of practice agreement, provided the cases were approved by the Association's solicitors. A number of cases have been referred for legal action, and the necessary steps have been taken. In one case High Court proceedings were taken on the advice of the solicitor. In this instance an interim injunction was granted preventing the acting practitioner from dealing with moneys received by him on the absentee's behalf otherwise than in accordance with the scheme.

Sale of Milk (Restriction) Order

The *Supplement* to the *British Medical Journal* for June 14 contained correspondence which had passed between the Association and the Ministry of Food on the Sale of Milk (Restriction) Order. The Association considered that many of the features of the scheme were unsatisfactory and made representations and suggestions to the Ministry, more especially on the list of diseases for which extra milk might be obtained and the requirement that the medical certificate, which showed the nature of the

disease, should be given to the dairyman. The Ministry promised that the points raised by the Association should receive full consideration in the general revision of the scheme which was contemplated, and in the meantime made an arrangement under which the practitioner would send to the Food Office a list of the cases in which he had issued certificates, thus obviating the handing of a medical certificate to the dairyman. The Ministry has now sent for the Association's observations a revised scheme, which is a great improvement on the original. The list of diseases is divided into two parts, the first containing the more serious diseases for which extra milk is required and the second relating to temporary incapacity. The medical certificate is sent to the Food Office, which authorizes the supply of extra milk.

First-aid Posts

The Select Committee on National Expenditure recommended in its fourteenth report that certain economies should be effected in connexion with the duties of medical practitioners at first-aid posts and the remuneration paid to them. It recommended that: (a) The difference in the amount of attendance required of doctors at posts in more vulnerable and less vulnerable areas should be abolished. (b) Three attendances a week are unnecessary and once a month is not enough. (c) Training to maintain the efficiency of first-aid posts should be largely in the hands of a trained nurse. The doctor in charge should be relieved of all routine duties of administration. (d) The annual fee (£75 or 20 guineas) should be discontinued.

A letter was subsequently received from the Ministry of Health expressing its own views on these recommendations and asking for the observations of the Central Medical War Committee. The letter stated:

"As regards (a) the Minister is disposed to share the view of the committee that there is no longer any justification for the difference in the amount of attendance required of the doctors as between posts in vulnerable areas and those in non-vulnerable areas. This difference was brought about by Circular 1918 at a time shortly after the outbreak of war, when the posts in vulnerable areas required a considerable amount of concentrated work to bring them to a proper state of efficiency, not only because they were likely by reason of their situation to be called upon to deal with the effects of heavy air attacks, but because they were kept constantly in commission with whole-time personnel who consequently required fairly continuous supervision at that stage of the war. Now, however, the additional work of training and organization has largely been completed, and what is required is to maintain the efficiency of the post at an adequate level.

As regards (b) the Minister finds it difficult to lay down any general rules as to the amount of attendance required. He agrees that attendance three times a week is not necessary in the present circumstances and that attendance once a month would usually be inadequate, and he has come to the conclusion that within these limits it must be left to the medical advisers of the local authority, in consultation with the doctors concerned, to make such arrangements as the circumstances require. The Minister feels sure that he can rely on the doctors giving such attention to the work of training as is necessary to maintain the efficiency of a team in which they can justifiably feel a personal pride.

As regards (c) the Minister does not consider that the responsibility for training could be entirely delegated to the trained nurse if only for the reason that, as experience has shown, changes in the nature of the training may frequently have to be made to meet changing conditions of warfare. The nurse should assist, but the ultimate responsibility and supervision should remain with the doctor. Indeed the main duty of the doctor should be to keep the standard of training of the existing personnel to a proper level, to attend to the training of any new recruits to the post, and to ensure that these recruits are properly absorbed into the organization and that a proper team spirit is thus maintained. The routine duties of general administration and supervision of stores no longer require the personal supervision of the doctor appointed to the post, but could be undertaken by other personnel or by the appropriate officer of the scheme-making authority.

As regards (d) it will be apparent that if, as suggested above, the distinction between the vulnerable and non-vulnerable areas is abandoned, some adjustment of the fees will be necessary unless the profession are prepared to accept the suggestion of the committee and to make their services available without remuneration.

The Central Medical War Committee appointed a special committee to consider the matter, and this committee expressed the opinion that the recommendations of the Select Committee showed "a lack of understanding and appreciation of the nature and extent of the work of doctors in the organization and training of the personnel of first-aid posts in both vulnerable and non-vulnerable areas." A letter was sent to the Ministry of Health conveying the following recommendations:

(a) Under present conditions there should be no differentiation in the duties required of practitioners in charge of the posts in both vulnerable and non-vulnerable areas.

(b) The personnel of all first-aid posts in all areas should be kept fully trained. To ensure the efficient training of personnel, including new recruits, and the maintenance of team spirit and morale, the first-aid post medical officer should attend not less than three times a week.

(c) The responsibility for the training of the personnel should remain with the practitioner in charge of the post, who may at his discretion delegate certain functions under his immediate supervision. In the interests of efficiency and effective control the responsibility for general administration and supervision should also be retained in the hands of this practitioner.

(d) The payment of £75 per annum to the practitioners in charge of the posts in vulnerable areas should not be reduced but should be made applicable to all areas.

A deputation placed these resolutions and the arguments for them before officials of the Ministry of Health.

Medical Certificates

The Association is aware of the extra burden imposed on medical practitioners by requests for medical certificates for various purposes arising from wartime conditions, and the subject is being discussed with the Government Departments concerned. These certificates include those applied for by persons claiming to be unfit for transfer to work away from their homes; for persons entering factory employment; for appellants against fire-watching duty; and special certificates in connexion with air-raid injuries. The request for certificates for one-day absences from work in connexion with the attendance bonus scheme is particularly onerous, and the Council has issued the following letter to Divisions in colliery areas:

"The attention of the Association has been drawn to the requests now being made or about to be made, as a result of the operation of the Attendance Bonus and the Essential Work Order, for medical certificates for one-day absences from work. It is clearly impossible in the vast majority of cases for practitioners conscientiously to give such certificates based on ascertainable physical signs, and this request can only result in embarrassment to both doctors and miners without achieving the object for which it has been designed. In these circumstances the Association advises colliery practitioners to decline to undertake, as a general procedure, the issue of such certificates.

"It is suggested that Division executives and organizations of colliery surgeons should intimate this decision to local miners' and owners' organizations."

The whole question of the certificate burden and the lack of co-ordination between Government Departments in requiring medical certificates has been the subject of strong representations and is now under discussion between the Association and the Ministry of Health.

Industrial Health Committee

It is hoped that the report of the Committee on Industrial Health will be completed very shortly. Since the publication of the Annual Report the committee has issued to Divisions a circular suggesting that they should consider making contact with employers in the neighbourhood with a view to securing for general practitioners facilities for seeing something of factory life in action, and for making themselves acquainted with the work of their patients or of any one patient, so that this knowledge will help them to decide how far a patient's health is affected by his work and to advise and prescribe accordingly.

Fire-watching

The Association has discussed with the Ministry of Home Security the liability of medical practitioners to undertake fire-

watching duty. A full statement of the position was printed in the *Supplement* for May 10, 1941. Briefly, medical practitioners are exempt from registration and enrolment under the Civil Defence Duties (Compulsory Enrolment) Order, but they are liable under the Fire Prevention (Business Premises) Order. The Ministry of Home Security has been asked for a statement confirming that medical practitioners will be exempt from registration in connexion with the new fire guard.

Transfer of Doctors' Maids

Many practitioners are experiencing difficulty in consequence of the Registration for Employment Order for Women. When the scheme was first announced the Association approached the Ministry of Health to ascertain whether it was likely that doctors' receptionists and maids would be transferred to other duties. The Ministry's reply that no guarantee could be given and that each case would be decided by the interview was not satisfactory, but it was decided to wait until the interviewing had begun, to see how the scheme would work. From correspondence now being received from practitioners it would appear that the nature and importance of the work of a doctor's maid are not fully appreciated by the officials at the employment exchanges. A letter, which was printed in the *Supplement* of August 2, has, therefore, been sent to the Ministry of Labour asking that more consideration might be given to individual cases.

Medical Planning Commission

The Medical Planning Commission, the appointment of which was reported in paragraph 4 of the Annual Report, held its first meeting in May, and a full report of the proceedings was published in the *British Medical Journal* for May 17. The Commission increased the representation of general practice by adding four more general practitioners to its membership, and it appointed six committees—namely, a General Practice Committee, a Special Practice Committee, a Public Health Committee, a Hospitals Committee, a Teaching Hospital Committee, and a Co-ordination Committee. The subject committees have now begun their work by considering the general nature of the problems within their respective spheres.

Petrol

In view of complaints of difficulties caused by cuts in the supplementary allowances issued to medical practitioners representations have again been made to the Petroleum Department. The Department has given an assurance that there is no intention to withhold petrol required by doctors for the discharge of essential services necessarily involving the use of a car. Despite this assurance cases of difficulty still occur, and the position cannot be considered wholly satisfactory. The Association will continue to do everything possible, both in its negotiations with the Department and by investigating individual complaints through the medical liaison officers, to ensure that legitimate claims are reasonably considered and just grievances promptly remedied.

Considerable apprehension has been caused by the announcement of a proposed compulsory Order relating to a daily log of journeys undertaken by recipients of supplementary rations. When this announcement appeared a prompt protest was made by the Association on behalf of the profession. Discussions with the Petroleum Department are still proceeding, but it is hoped to publish a statement on the subject in the *Supplement* next week.

Car Repairs

Repeated representations have been made to the Ministry of Transport regarding the difficulties experienced by medical practitioners in obtaining spare parts and repair facilities for their cars. The institution of a system of priorities for essential road transport, including doctors' cars, has been fully considered by a special committee set up by the Ministry, but has been judged to be impracticable. Every effort will be made, however, to ensure that cars used for essential work will be immobilized as little as possible. Doctors who fail to secure the necessary facilities by their own efforts should apply to the Certifying Officer of the Ministry at the office of the Regional Transport Commissioner.

Lectures on Gas and Air-raid Casualties

The Association is co-operating with the Ministry of Health in arranging lectures on the diagnosis and treatment of gas casualties to supplement the printed information recently issued by the

Ministry to all practitioners in England and Wales. The number of experts on this subject being limited, it is necessary to confine these lectures, for the present at least, to the larger centres of population in the more vulnerable areas. The speakers are provided by the Ministry and the arrangements are made by the local Divisions of the Association, the cost of printing and posting the necessary notices being defrayed out of the funds of the Divisions.

Divisions in comparatively "unblitzed" areas have been authorized to arrange, if they so desire, lectures on air-raid casualty work by speakers with experience of "blitz" conditions. The Ministry of Health have offered to assist, through their regional hospital officers, in the selection of suitable lecturers. Printing and postage costs and any out-of-pocket expenses of the lecturers are borne by the Divisions.

Alien Practitioners

More than 400 alien practitioners have now been selected for approved civilian medical appointments under the Medical Register (Temporary Registration) Order, 1941. The posts secured by these practitioners are mainly of a comparatively junior nature in hospitals and institutions. The Central Medical War Committee has undertaken a laborious task in connexion with the administration of the Order. It serves as a co-ordinating agency, obtaining the necessary permits for individual practitioners from the Security Departments, submitting names of available candidates on request to employing authorities, and arranging for registration in the *Medical Register* to be effected when approved employment has been offered and accepted.

Discussions are proceeding at present regarding the advisability of amending the Order by extending the list of overseas territories to which it applies and adding to the categories of approved employment. It is thought that, in view of the extreme shortage of British practitioners available as locumtenents and assistants in general practice, it may be advisable, under carefully defined conditions, to permit temporarily registered practitioners to undertake this work for the duration of the present emergency only. There is no question of such practitioners being allowed to practise privately on their own account, to continue as registered medical practitioners after the war, or to undertake medical work in this country after the war.

Other Matters Recently or at Present under Consideration

These include: income limits for Hospital Contributory Schemes as a result of the raised income limit for insured persons; National Ophthalmic Treatment Board arrangements from January 1, 1942; Ministry of Pensions scales of remuneration; augmentation of salaries of district medical officers in reception areas; medical care of civilian population housed in huts; and the scale of remuneration under the National Deposit Friendly Society.

COURSE FOR HOME GUARD MEDICAL OFFICERS

At the request of the Central Medical War Committee the War Office has arranged a short course of instruction for Home Guard medical officers specially adapted to their Home Guard work. The course will be held at 11 Corps R.A.M.C. School, St. John's College, Cambridge, from Thursday, September 11, to Tuesday, September 16, 1941. It is open to all medical officers commissioned as such in the Home Guard, and those desiring to attend this course should communicate immediately with the Secretary of the Central Medical War Committee, B.M.A. House, Tavistock Square, W.C.1, and in any case before Wednesday, September 3. Officers attending will be asked to report to the Commandant at St. John's College, Cambridge, between 14.00 hours and 16.00 hours on Thursday, September 11. Uniforms should be worn. Officers will be accommodated in St. John's College, bed and blankets being provided, and will mess in the College Hall. The charge for messing will be 9s. 6d. per day. Officers should bring their civilian ration card, notebooks, and pencils. The course will disperse at 11.00 hours on Tuesday, September 16, 1941. Cheques will be accepted in settlement of messing account. A copy of the syllabus will be forwarded in due course to those intimating their desire to attend.

It is hoped that there will be a generous response to this opportunity. The course will be limited to thirty officers, and will not be held unless at least twenty intimate their desire to attend.

Correspondence

Medical Planning and a State Medical Service

SIR,—I imagine that by this time an official asterisk, with the intimation "This correspondence is now closed," may have put a summary closure to the many letters on this subject. But I can plead ignorance over here, as I have only recently seen the *Journals* for April and May, which were lent to me by a colleague isolated in the prairies like myself. I confess that the letters from your many correspondents on medical planning and the allied matter of a hypothetical State Medical Service have disturbed me a good deal. Unfortunately the copy outlining the proposed scheme put forward by Dr. Pybus was not among those handed over to me, so I am ignorant of its exact details, its merits, or its faults. But from perusal of the letters supporting or opposing his suggestions I have a fair idea of what those proposals were. And I must immediately align myself with the opponents of his scheme.

Much has been made in the correspondence about the age of the members of the Medical Planning Commission, their right to speak for younger men, and the wider question as to how much a State service would be welcomed by the public apart from the profession itself. I believe that, as a young member of the genus "medical practitioner," I have a right to give my views, as, indeed, what is decided or proposed will affect me and all my generation of practitioners all our days. So I shall say my say, and try not to make the matter too personal.

Before the war I was a partner in practice in a North of England country town, one of these ideal country towns where the other medical men—all nine of them—do not indulge in undignified rivalry and where all are admitted, if they so desire or are worthy, to the staff of the local country hospital. For my share in the practice I borrowed, and still owe, a considerable sum. And so, after four years, to August, 1939, when, as a member of the R.A.F.V.R., I was called up for service; and from there by way of a Bomber station at home to France and Dunkirk; by way of a tented existence in Yorkshire (with my hospital in an empty fish-and-chip shop) to an interlude in a north-western coastal town working in a large Service hospital; and, finally, after three transatlantic crossings, to the prairies of Canada in charge of a splendidly equipped Service hospital.

Thereafter, who knows? But when it is all over I hope to return to a life like that which I was called upon to leave for a while: trust, friendship, willingness, and an absence of rigid regulations and formality. And meantime, while I (as well as hundreds of others like myself) am absent the future of medical practice is being discussed and planned and plotted. I freely confess that I am not proud of living over here in comparative luxury and perfect safety while my family, my friends, and my colleagues at home have less easy paths to tread. But the choice was not mine. What I do suggest, however, is that this very debatable question of a State Medical Service, in fairness to those of us who are away, can only be decided in two or three ways. My first point is that those of us in the Services are likely to be affected as much as—or even more than—those in civilian practice by the results of the deliberations now in progress. We expect to return with thirty to forty years' medical work ahead of us. Surely we are entitled to say whether we agree or disagree with the commitments liable to be made in our name in our absence!

To my mind there are only two fair alternatives. One is to await the return of absent practitioners and let them have the major share in the construction of the life they are going to lead, the work they are going to do. The other is to circulate all the profession with a draft scheme for their approval or condemnation. If State medicine must come, then those already in a State service should be given the chance of assessing what their life will be like in an alternative service. First of all our patients should be given their choice as regards a form of State service. Then we should be given a fair deal, a fair explanation of what is proposed for our future and in the disposal of our past liabilities in all circumstances. We expect that fair deal while we are absent on active service. We rely upon the trustees who are left behind.—I am, etc.,

W. H. GOSSIP.
Squadron Leader, R.A.F.V.R.

State Medical Service

SIR.—The question no longer is, Are the medical profession in favour of a State service? but, rather, What kind of a State service are we prepared to accept if the public signify their desire for this type of service or are led to believe that a State Medical Service will be best for the health of the country? The more the profession air their views in your columns and also at medical meetings, the more likely we shall be ready to meet this complete change if or when it comes.

It seems important that such a service shall be administered, in the main, by the medical profession, and it would be a good thing that those doctors who show administrative capacity should be encouraged to improve their technique in order that we can meet and cope with the civil servants on their own ground. In the cities, clinics would be more adequately staffed and equipped than the present individual surgeries. There is also no doubt that we should all benefit by more supervision and discipline, which are almost entirely lacking in the present national health service. The correlation of all the medical services would also tend to prevent the present overlap between the public health and other services.

Two main arguments against a State service are: (1) loss of personal contact with patient; (2) loss of independence. Our independence has already been largely lost since the present war began, and providing we can offer to the Government a satisfactory State service we should still be able to keep enough independence to satisfy the most exacting. Apart from the country districts we no longer have the same control of our patients' medical duty, and I feel sure that the individuality of each doctor will continue to assert itself in whatever kind of service we are finally in.—I am, etc.,

Larkhill, Wilts. Aug. 16.

R. C. L. BURGESS.

SIR.—Dr. G. Llewellyn Davies's letter (*Supplement*, August 2, p. 15) is sensible and to the point. To-day general practice is as much a business as a profession, and it will be increasingly so, to the detriment of the medical art, so long as practitioners have to compete with one another in their efforts to provide adequately for their dependants and for retirement. We are trained to be professional gentlemen; we are compelled to be business men. Every doctor knows of cases in the profession where men, through diffidence in money matters or lack of business instinct, neglect the presentation and settlement of accounts and thereby create financial chaos for themselves. Do we do anything to help them or the others in the profession who for various reasons are unfortunate? By no means. Our present state of organization and co-operation (or lack of it) holds out no helping hand to the unlucky; and many a man in spite of sound professional ability is unlucky in the economics of his life's work.

Let us, as Dr. Davies says, have done with humbug and examine the problem in a clear light. The practice of medicine is one of the most important and most exacting of the services to the public, and as such the livelihood of those engaged in it should be guaranteed. That a man is lacking in business methods, deficient in "bedside manner," or has sunk his capital in a "rocky" practice is in no wise a reflection on his knowledge of the work he has been educated in. Nevertheless, the possession of these qualities and luck in "hitting on the right place" are more often the measure of worldly success than ability and endeavour to deserve well of the profession.

If a State Medical Service will remove these evils let us have

Most practitioners on giving the matter thought will, I am re, agree with Dr. Davies.—I am, etc.,

Strichen, Aberdeenshire, Aug. 3.

WILLIAM HARKINS.

State Medical Service: An Analogy

SIR.—I am astonished and dismayed by the complaisance with which the prospect of an all-embracing State Medical Service is regarded by many who have enjoyed the privilege of free practice. I cannot help believing that the State they envisage is not the State of experience but a "dream State"—a State that never was on sea or land.

In the last twenty-six years I have done medical work for the State in many departments—the R.A.M.C., the Ministry of Pensions, the Ministry of Health (as a panel practitioner), the Ministry of Labour (as a member of recruiting boards), the Post Office Medical Service—and have worked in what is next door to a State

service—the School Medical Service of London. I have also practised on my own account for twenty years. Unless I utterly deceive myself I have done far better clinical work and been of far more use to my fellow citizens as a family doctor working independently of any State Department and remunerated by fees agreed between me and my patients than I have done when the State has had a hand in the matter. It is not that I am not ready to give my best work to the State or that I find a salary or a capitation fee less conducive to effort than the "piece-work" plan of private practice, though, by and large, I think private patients reward us far more nearly according to our deserts than does the State, but it has been my constant experience that the State does not want my best work, does not really like it, and very frequently has stood between me and the doing of it.

In the course of practice we may find ourselves trying to serve and help a very irritating patient. He is elderly, conventional, vain, and very ill informed. He has no conception of the nature of clinical medicine and is quite unable to tell good work from bad; he is at once dictatorial and timid, for ever issuing instructions but unable to take a bold decision, morbidly careful of appearances and afraid of public or private criticism. He is blown about by every wind of doctrine and is constantly asking us to pursue vain and futile lines of investigation and treatment, mistaking theory for fact and gesture for deed. He insists on being treated for every little ailment by a team of specialists, the notion of personal responsibility being outside his scale of values. Sometimes he insists on paying us for doing nothing; sometimes he disputes our accounts for well-earned fees; and though well off he is constantly fretting about expense. It is, of course, quite impossible to give such a man the best or even good medical service. He does not understand it, dislikes it, and will not have it.

Now one such patient in a practice consisting in the main of decent, sensible folk whom we are free to treat *secundum artem* can be borne. He does not monopolize our time or energy, and can be trusted to change his medical adviser before he becomes quite intolerable. But suppose one day a fancy takes him and he comes, all smiles, with a proposal which he is sure is as much for our good as his. He invites two of us to become his whole-time medical staff. Our hours of work are to dovetail neatly so that we shall know precisely when we are and when we are not responsible for his health; our modest salary is to be paid regularly into our bank; there are to be holidays with pay, and when we are retired at 65 we may be sure of a little pension; his library and private laboratory are at our disposal; and we undertake to attend classes at a neighbouring medical school to keep us up to date. We are to attend him, and perhaps his immediate family, as and when required, carrying out such investigations and treatments as he may request (we can trust him, he says, to ask us for nothing unorthodox), and in specified circumstances we are to call in a consultant from the list with which he will supply us. We are not to practise on our own account. The contract is for life, and, indeed, he hopes that our sons will take it on from us when we, unfortunately, have to retire. This is the proposition, and it is useless to argue with him; we must take it or leave it. Knowing the self-deceived and muddle-headed old tyrant for what he is, can anyone who values his professional freedom, who reveres the art of medicine, and who sincerely wishes to give of his best to his fellow citizens hesitate one moment to refuse it?—I am, etc.,

Hamstead, Aug. 16.

LINDSEY W. BATTEN.

Payments to Insurance Practitioners

SIR.—The decision of the Panel Conference to accept the Ministry's offer of an inadequate capitation fee makes it essential that N.H.I. practitioners should receive, and be satisfied that they are receiving, the full capitation fee to which they are entitled.

In the *Journal* of August 9 (p. 215) Miss Horsburgh, on behalf of the Minister of Health, is quoted as having stated that the number of insured persons in Great Britain on December 31, 1939, was: men and boys 14,204,000, and women and girls 7,243,000—that is, a total of 21,447,000. At the rate of 9s. a head, the sum payable to N.H.I. practitioners should therefore have been approximately £9,650,000. In the *Journal* of August 16 (p. 252) Mr. Ernest Brown is quoted as having stated that a sum of £7,674,127 was paid in 1940 to doctors under contract with Insurance Committees in respect of treatment. How is this

difference of nearly £2,000,000 to be accounted for? Large numbers of insured men have, of course, joined the Services, and these must to some extent be offset by the large numbers of women and boys who have been taken into the war industries, as well as previously unemployed men whose entitlement to medical benefit had lapsed. I think that N.H.I. practitioners are entitled to a full explanation.—I am, etc.,

Manchester, Aug. 17.

ARNOLD GREGORY.

New Capitation Fee

SIR.—Great indignation is being expressed not only in Birmingham but everywhere. Appeasement will never get us anywhere; the profession must take off the gloves. "The time is not opportune." Will it ever be opportune? Never until the old heads on the Insurance Acts Committee are scrapped and we have younger representatives who come forward with tanks and brains. If there are any "worms" in the profession, and I doubt it, the worms are the members who never attend meetings and only grouse. Dr. Gregg hit the nail on the head: "If they have chosen worms, why have they chosen them?" I now appeal to the aged members and the Insurance Acts Committee to resign, and give way to new and, I trust, younger representatives who will have nothing to do with appeasement. "The King is dead; long live the King!"—I am, etc.,

Birmingham, Aug. 17.

F. A. L. BURGESS.

* The election of the Insurance Acts Committee will take place shortly.—ED., B.M.J.

Medical Certificates

SIR.—I am interested in the correspondence on the abuse of panel certificate. Some years ago I discovered that the Ministry of Health itself connives at this practice of inspecting certificates so that its employees do not have to procure private certificates. I took the matter up with the Ministry and through your columns, but attained to no satisfaction whatever. Can any of your correspondents expect private employers play the game according to the rules when those who frame them treat them with contempt?—I am, etc.,

London, S.E., Aug. 9.

DONALD M. O'CONNOR.

New Entrants to Health Insurance

SIR.—I understand that in January, 1942, about 450,000 non-annual workers with incomes between £250 and £420 per annum will become compulsorily insured. Is any provision being made for the loss of these patients to the practices of doctors who may be away on military service? Would not the fairest way be to postpone the scheme coming into operation until after the war?—I am, etc.,

London, S.E.6, Aug. 9.

MALCOLM COWAN.

* The Secretary of the B.M.A. states that the point raised by Mr. Cowan is under consideration by the central Protection of Practices Committee, and it is hoped to make an early announcement on the subject.

Publicity for Insurance Acts Committee

SIR.—A Panel Conference met on July 31 to decide a question that affects every panel practitioner. How many of them know the result? I suggest that the Insurance Acts Committee should seriously consider the necessity of arranging for more publicity of its work. It has been negotiating with the Minister of Health since the beginning of the year, and a report was sent to panel committees last month, but it was not published in the *Journal*. The contents were disclosed to doctors in those areas where a general meeting of practitioners was convened, though probably only to those who attended the meeting. Representatives who went to the conference realized that opinion is divided and deeply disturbed, as is borne out by the small majority of only nineteen votes for the resolution that accepted the Government's offer.

If and when an account appears in the *Journal* members of the B.M.A. will have the information, but not that considerable number of non-members. A decision so important ought to be made known at once to all interested, and in my own area that has been done by the panel committee. Further, in order that doctors may form properly instructed opinions they must be

kept informed by the I.A.C. of what is happening. There are large numbers of doctors who know little or nothing of what is done on their behalf by the I.A.C. and do not even know that it is a committee which includes many members that do not belong to the B.M.A., and that in fact these latter could form a majority. Consequently both the I.A.C. and the B.M.A. come in for severe criticism.

The Medical Practitioners' Union send out circulars from time to time which go to all doctors, and which, besides containing statements of fact, also convey the opinions and policy of the union. To many doctors it must appear that this union is the only organization that is really interested in their welfare. I hope that members of the I.A.C. will ponder carefully this question of better publicity, and study what was said with obvious sincerity by speakers at the conference.—I am, etc.,

Weymouth, Aug. 10.

J. A. PRIDHAM.

* The Secretary of the B.M.A. states: Reports of meetings of the Insurance Acts Committee at the negotiations with the Ministry of Health have been discussed and appeared in the *Supplement to the Journal* of June 28 and July 26, and Panel Committees were informed at an early stage of the correspondence which passed between the committee and the Ministry.

"Pure Despotism"

SIR.—Most of us who have worked the national health insurance system since its inception will be inclined to smile at the description, quoted by Dr. Turtton from Lord Hewart's *The New Despotism*, of the treatment of panel doctors under the N.H.I. Acts as "pure despotism." The notion that doctors are bullied by despotic officials or prevented by fines from prescribing adequate medicines is pure delusion. While his eminent and noble lordship was writing this nonsense, I and others were prescribing insulin at a cost of 25s. a week (in its early days) for panel patients. A working-class patient under N.H.I. benefit can have medicines which private patients of the same class could not possibly afford.

Of course, under any system of treatment, public or private, economic facts compel some limitation of the cost of treatment. It is unjustifiable to prescribe the elegant productions of commercial drug firms in private or panel practice if the same results can be got by non-proprietary drugs. Or, to take a simpler example, the standardized digitalis leaf tablet is cheap and, according to most cardiologists, as good a preparation as any for most heart cases, yet many practitioners habitually prescribe the more expensive and unnecessary digitalin.

But let us call another witness for Lord Hewart's charges from a very different quarter. In a Communist booklet (*Condition of Workers in Britain, Germany, and U.S.S.R.*, published 1939) Kuczynski, attacking the N.H.I., not because it is socialistic but because it is capitalistic, says: "A worker has to pay for medicine as a matter of course or because the insurance scheme does not provide as good a medicine as is demanded by his illness." The value of this assertion may be judged by further quotations from the same author. "Good physicians in the capitalist countries spend most of their time on rich patients and are often interested in poor patients mostly for the purpose of experimenting on them or if the sickness of the worker is of a rare or interesting kind." The humour of this will appeal most to the honorary surgeon of a voluntary hospital after three hours' intensive work in his outpatient department or operating theatre. Again, "the dream of most country doctors is to spend as much time as possible at the bedside of the gentry." It is to be feared that most country doctors find that there is much difference between the dream and the reality.—I am, etc.,

Bradford-on-Avon, Aug. 17.

T. T. APSIMON, M.B.

A Panel Doctor Repents

SIR.—*Mea culpa! Mea maxima culpa!* I pour ashes upon my head, for I have sat among the gods and have cried scorn upon the I.A.C. upon the stage. But I repent me of my hasty judgment, and am sorry for my bitter words, and will strive to make amends. I have indicted them of supineness, of want of courage, and even of levity towards the interests of their constituents.

Sir, I withdraw it all; for I have attended a panel conference, and it has been revealed to me that the I.A.C. has but faithfully reflected the opinion and the will of the majority of those who have elected them to their high office. At this conference I

found that out of forty-nine relevant propositions nineteen were definitely defeatist in character and calculated to increase the non-resistance party. Further, it appeared that no less than 55% of the delegates were themselves defeatists and voted accordingly.

I am driven, therefore, to the conclusion that the fault of the feeble representation of the views of so many of the profession is due to the fact that the panel practitioners themselves elect to their local committees defeatist representatives, whose motto, typical of their kind, is "Half a loaf is better than no bread." These local panel committees in their turn appoint a super-defeatist to be their delegate to the Conference, and frequently supply him with a defeatist proposition to support and promulgate there.

Sir, we know too well how a political autocrat deals with defeatists. He tramples them down into the mud. Our only hope for the future, then, lies with ourselves. We must choose stronger men to make up our local committees, who will see that their delegates at the Conference will reinforce the I.A.C. with the support of the whole profession when it takes a strong line with the Minister. Let us cease reviling the I.A.C. and make a more careful choice of our representatives at the next election to the Local Panel Committees.—I am, etc.,

Diss. Norfolk, Aug. 4.

J. CUTHBERT PEARCE.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

ROYAL NAVAL VOLUNTEER RESERVE

W. Lennon to be Temporary Surgeon Lieutenant.

Probationary Temporary Surgeon Lieuts. J. F. Donovan, A. L. Young, A. McE. Smith, W. St. C. Symmers, G. O. C. Davies-Webb, A. G. E. Pearce, R. G. W. Moore, E. Fowler, W. W. Tennant, W. B. Mumford, F. B. T. T. Drake, W. S. Johnston, and J. A. Fisher to be Temporary Surgeon Lieutenants.

ROYAL ARMY MEDICAL CORPS

War Substantive Captain F. J. Fell has relinquished his commission on account of ill-health, and resumes the rank of Lieutenant.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Lieut. A. B. Cowley, from Royal Artillery, Reserve of Officers, to be Lieutenant.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Major N. W. Kidston, from Territorial Army Reserve of Officers, R.A.M.C., General List, to be Lieutenant, and has relinquished the rank of Major.

War Substantive Captain R. C. Tudway has relinquished his commission on account of ill-health.

Lieuts. G. D. Malcolm and P. J. O'Reilly have relinquished their commissions on account of ill-health.

ROYAL AIR FORCE

Group Captain F. N. B. Smart, R.A.F. (ret.), has relinquished, at his own request, the rank of Group Captain whilst being re-employed with the Royal Air Force and assumes the rank of Wing Commander.

Flight Lieut. I. Mackay has been granted the war substantive rank of Squadron Leader.

Miss Agnes C. Gillan and Miss Alison M. Clark have been promoted to the relative rank of Flight Lieutenants.

Miss Emmie D. Fenwick has been granted the relative rank of War Substantive Flight Lieutenant.

Miss Marjorie M. Dobson has been promoted to the relative rank of Flight Lieutenant in the Royal Air Force, and not the Royal Air Force Volunteer Reserve as announced in the *Supplement* of July 26 (p. 14).

Miss Janet MacL. Mackay has been granted a commission, with the relative rank of Flying Officer.

ROYAL AIR FORCE RESERVE

Flight Lieut. R. G. James has been granted the war substantive rank of Squadron Leader.

AUXILIARY AIR FORCE

Flight Lieut. N. R. Smith has been granted the war substantive rank of Squadron Leader.

ROYAL AIR FORCE VOLUNTEER RESERVE

R. Howarth to be Squadron Leader.

Flight Lieut. (temporary Squadron Leader) A. W. Badenoch has been granted the war substantive rank of Squadron Leader.

Flight Lieut. P. J. Nyhan has resigned his commission.

Flight Lieut. W. McP. Cross has relinquished his commission on account of ill-health.

To be Flight Lieutenants: R. D. Henderson, I. D. Grant, A. G. Leigh, C. Reid, A. T. M. Roberts, and C. H. Stewart-Uss.

The notification in the *London Gazette* of July 25 concerning Flight Lieut. W. MacP. Cross has been cancelled.

Flying Officers R. W. Lass, P. T. D. Lynch, R. O. Gillhespy, S. J. Hadfield, J. G. Paton, T. Fenwick, I. W. Hockley, J. E. Horrocks, R. N. Houlding, J. O'Meara, C. E. Astley, T. L. Stote, J. A. S. Green, T. M. Brand, L. H. Buckland, P. Murphy, D. O. Dickie, A. G. Marshall, J. O'Leary, D. S. Pattison, W. D. Doey, E. H. Jones, C. R. Savage, J. P. Bentley, R. Crawford, R. Cunningham-Jones, W. W. McGrath, T. Akroyd, H. W. Smithies, and T. Taylor to be War Substantive Flight Lieutenants.

Flying Officers (on probation) H. J. Knox and R. Oddie have been granted the war substantive rank of Flight Lieutenant.

BRITISH MEDICAL ASSOCIATION ANNUAL GENERAL MEETING

Notice is hereby given that the Annual General Meeting of the British Medical Association will be held in the Great Hall, British Medical Association House, on Thursday, September 11, at 12.30 p.m.

Business

1. Minutes of meeting held on October 28, 1940.
2. Appointment of Auditors.
3. To receive and approve the statement of accounts of the Association as published in the *Supplement* to the *British Medical Journal* of May 17, 1941.
4. Any other business.

G. C. ANDERSON,

Secretary.

MEETING OF REPRESENTATIVES

A special meeting of Representatives of Home Divisions of the British Medical Association will be held at B.M.A. House, Tavistock Square, W.C., on Thursday, September 11, at 12 noon, and will continue on the following day. The Executive Committee will meet at 10 a.m. and the Council at 11 a.m. on September 11.

Special Meeting of Representatives of Home Divisions,
12 noon (continuing on following day). |

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following postgraduate courses for Final F.R.C.S. candidates: (1) comprehensive revision course, every morning, 10 a.m. to 1 p.m., from September 29 to October 17; instruction will include clinical teaching in the wards and out-patient department, x-ray and museum demonstrations, lectures, tutorials, and written papers; (2) practical operative surgery on the cadaver, on Mondays, Thursdays, and Fridays, at 2 p.m., from October 6 onwards. Both these courses will be given at the Royal Cancer Hospital.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*St. Mary Islington Hospital*, Highgate Hill, N.: Wed., 2 p.m., Final F.R.C.S. Clinical Course. *Royal National Orthopaedic Hospital*, Stanmore: Sat., 2.15 p.m., Final F.R.C.S. Orthopaedic Course. *London Chest Hospital*, Victoria Park, E.: Tues. and Thurs., 2 p.m. to 4 p.m., M.R.C.P. Course in Chest and Heart Diseases. *Brompton Hospital*, S.W.: Mon. and Thurs., 5 p.m., M.R.C.P. Course in Chest Diseases. *West End Hospital for Nervous Diseases*: Tues. and Fri., 3.30 p.m., M.R.C.P. Course in Neurology. *Royal Chest Hospital*, City Road, E.C.: Wed., 3.30 to 5 p.m., M.R.C.P. Course in Heart Diseases.

BRITISH POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*Daily*, 10 a.m. to 4 p.m., M.R.C.P. Course in Clinics and Operations, Obstetrical and Gynaecological. *Mon.*, 1.30 p.m., Postgraduate Course in War Surgery of Extremities commences. *Tues.*, 11 a.m., Paediatric Clinic, Dr. R. Lightwood. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical). *Thurs.*, 2 p.m., Dermatological Clinic, Dr. R. T. Brain; 2 p.m., Dr. Duncan White. *Fri.*, 12.15 p.m., Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. V. B. Green-Armlyage.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Robertsbridge (Sussex) is vacant. Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by September 9.

APPOINTMENTS

EXAMINING FACTORY SURGEONS.—R. N. Bullock, M.B., Ch.B., for the Tipton District (Staffordshire); W. Eales, L.R.C.P.&S.Ed., for the Knowbury District (Shropshire); P. J. MacMahon, L.R.C.P.&S.I., for the Stillington District (Durham); J. F. L. Rose, M.D., L.M.S., for the Rainham District (Essex).

BIRTHS, MARRIAGES, AND DEATHS

DEATH

HERRIES.—On August 22, 1941, after a brief illness, Dr. Francis William Herries, aged 28, only son of Mr. Louis F. Guanziroli of Wimbledon.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 6 1941

THE MIDWIFERY OF A GENERAL PRACTICE

BY

R. A. RATCLIFF, M.D.

The following tables are taken from a detailed report on 603 midwifery cases attended by my two partners, L. C. W. Cane and S. C. Alcock, and myself during the five years 1935-9. The report was prepared in the manner suggested by the subcommittee of the Royal Society of Medicine (*Proc. roy. Soc. Med.*, 1927-8, 21, 1533), and it is interesting to compare the results with similar reports of lying-in hospitals.

Results

TABLE I.—Numerical Summary of All Cases

	No.	Booked	Emergency
Anterior position of vertex	317		
Posterior position of vertex	80		
Vertex—position unrecorded	153		
Breech presentation (excluding those produced by version)	40		
Shoulder presentation	7		
Face and brow presentation	6		
	603	417	186
Twins	19	11	8
Accidental haemorrhage	2	2	—
Placenta praevia	9	1	7
Post-partum haemorrhage	13	6	8
Albuminuria	17	11	6
Eclampsia	2	1	1
Acute inversion of uterus	1	—	1
Prolapse of cord	5	1	4
Forceps operations	167	60	107
Version, internal	16	1	15
"	3	3	—
"	12	6	6
Psychotic psychosis	2	—	2
Excise Caesarean section at term ..	4	4	—

Ratio Primip.
Multip. = 0.301

TABLE II.—Breech Presentation

Total No.	40
No. of babies dead or stillborn	9*
Corrected foetal mortality (4 out of 35)	11.4%
Primigravidae only:	
Total No.	17
No. of babies dead or stillborn	4†

* Includes 2 by drocephalus and 3 of 30 weeks' gestation.
† Includes 1 by drocephalus and 1 of 30 weeks' gestation.

TABLE III.—Forceps

	Booked	Emergency	Total
No. of cases	60	107	167
No. of foetal deaths	4	10	14
Foetal mortality	6.6%	9.3%	8.4%
Ruptured perineum and episiotomy	19	34	53
Maternal deaths	1*	1	2

* Died of pneumonia in hospital on the seventeenth day.

TABLE IV.—Internal Version

Indication	Booked			Emergency		
	No.	Infants Alive	Dead	No.	Infants Alive	Dead
Shoulder	1	1	—	5	5	—
Brow and face	—	—	—	4	3	1
Placenta praevia	—	—	—	2	—	—
" Failed forceps "	—	—	—	2*	—	—
Occipito-posterior	—	—	—	1†	1	—
Contraction ring	—	—	—	1	1	—

* 1 mother died from pulmonary embolism.
† 1 foet. perished during retention.

The foetal mortality in forceps cases is greater in those in nursing homes than at home, but I think this is a chance variation of no significance. No other difference is to be seen between the results in nursing homes and those at home.

Discussion

I find that we have not always noted the occurrence of morbidity when it has been no more than the degree of pyrexia laid down by the Royal College of Obstetricians and Gynaecologists. "Morbidity" is here to be interpreted as of a degree to cause some more enduring impression on the mind of the medical attendant, and all cases suffering from a pyrexial complication of more than three days' duration have been noted in our records.

There is a high incidence of all abnormalities, and this applies to forceps and version as well as to abnormal presentation. No estimate could be given of the number of normal cases to which these correspond: an uncertain proportion of the booked cases are booked because of expected abnormality or of previous abnormality. Emergency cases are those attended in response to midwives' requests for help, and are nearly all far advanced in labour when first seen—such patients are either in their own or nursing homes. But the results obtained in the treatment of abnormalities compare favourably with those of maternity hospitals.

Of many cases of abnormal labour the treatment is debatable, and there is room for much discussion whether the patient should be treated at home or, after delay and an ambulance ride, in hospital; in fact, there is no end to the questions that may require to be answered. Obstetrics can advance only by means of carefully kept statistics, by which we may criticize the value of old and new methods. Lying-in hospitals subject their results to such criticism, but I do not remember having seen such an analysis of results by general practitioners, and I therefore hope that these figures, though small by comparison, may be of value in answering the very important questions raised in the treatment of labour at home and in nursing homes by general practitioners.

DEFERRED MILITARY SERVICE

When the Central Medical War Committee recommends that the military service of a doctor of military age should be deferred, it does so on the understanding that the doctor will continue in his present appointment and will not apply for or accept any other employment without first getting the Committee's consent. In a circular on this matter to local and hospital authorities (Circular 24-0) the Ministry of Health points out that the practitioner is made aware of this condition at the time he is notified of the Committee's recommendation, and that the deferment is granted because of the work he is doing and not for any reasons of his personal suitability or otherwise for recruitment. Further, the Central Medical War Committee, with the Ministry's concurrence, has decided that in future any doctor who leaves such a post will be notified at once that it is proposed to recommend his recruitment, the Committee at the same time inviting the comments of the doctor's new employers and of the appropriate Local Medical War Committee. Hospital and public health authorities are therefore advised to satisfy themselves about the possible recruitment of any doctor of military age whom they propose to employ, and in case of doubt to get in touch with the Central Medical War Committee, B.M.A. House, Tavistock Square, W.C.1.

PETROL FOR DOCTORS

A circular recently issued by the petrol rationing authorities suggested that medical practitioners would in future be required to keep a log of their professional journeys. As this appeared to mean that details of each individual professional visit would have to be recorded, the Petroleum Department was promptly informed that, in the view of the British Medical Association, such a requirement was unreasonable. The matter has been discussed with officials of the Department, and it is clear that this unfortunate but necessary addition to the already heavy clerical work of the doctor will not be so onerous as was at first supposed.

The following statement on the subject has been included in a circular recently issued with the September-October supplementary allowances:

"Applicants who receive supplementary coupons in respect of private cars or motor cycles are reminded that they should keep a daily record of all journeys made. The record must show the places from and to which every journey was made, the business or professional purpose of the journey, and the mileage involved. Where, however, the car or motor cycle is used during any one day for the purpose of visiting, in connexion with the applicant's business or profession, different addresses all in the same district within a radius of fifteen miles from the start of the day's journeys, it is sufficient to record in respect of that day the number of addresses so visited, the approximate mileage covered, the district in which it was covered, and the purposes of the day's journeys. Applicants may be required to furnish a signed statement containing the above particulars in connexion with any future application for a supplementary allowance."

It will be seen that the majority of medical practitioners should be able to record the necessary details simply and briefly. For example, a general practitioner in the borough of St. Pancras will record the day's travelling in the following form: (1) Addresses visited: 20. (2) Approximate total mileage: 15. (3) District: St. Pancras. (4) Purpose: professional. In the case of a rural practitioner who may visit a number of villages in the course of the day a very brief description of the "district" will suffice. For instance, a doctor in Radlett whose round includes Shenley, Park Street, Aldenham, Elstree, and other villages may use the description, "Radlett and district." There is no need to describe in detail the "purposes" of the journeys; it is enough to state that they are professional.

The Association has tried to secure a further simplification of the log. It represented to the Petroleum Department that a doctor should be permitted to define the area of his practice at the beginning of the rationing period and to omit the daily description of the district. The Department declines to grant this further concession. It will be appreciated that the proposed compulsory Order will apply to all recipients of supplementary petrol, and that modifications to suit the convenience of particular professional groups are not easily arranged.

It will be noted that the summary of the day's travelling must include only journeys within a radius of fifteen miles from the start of the day's journeys. Longer journeys (with brief details of place visited, purpose of visit, and mileage) must be recorded separately in the daily log, but there is no question of petrol being refused for such journeys provided that they are necessary and that alternative methods of transport are impracticable.

While the need for this addition to the labours of overworked doctors is regretted, it is hoped that the evidence available in the log will make it easier in future to obtain from Divisional Petroleum Officers all the petrol that is genuinely claimed for professional use.

It appears that some Petroleum Officers are now requesting medical practitioners to produce a log for the July-August period. Those who have not kept a detailed record are advised to provide the best estimate they can and to explain that they have been awaiting precise instructions promised by their professional *Journal*. Owing to delays in the Petroleum Department it has not been possible to publish the above explanation earlier. It seems unreasonable to expect a daily record for July and August in the form to be laid down in an Order which is not yet in existence and which was referred to somewhat vaguely and prematurely in a circular issued at the end of June.

The Petroleum Department has declined to state specifically the purposes for which the basic ration may be used. The Minister, however, has recently referred to this ration as being "within the free use of the individual according to his conscience." Therefore, while no petrol should be consumed except to meet real needs, professional or domestic, it may be assumed that a doctor is not obliged to use any part of his basic ration in his professional work if he requires the whole ration for important domestic purposes.

THE MEDICAL ASSOCIATION OF EIRE (I.M.A. AND B.M.A.)

Cuman Dochtuiri Na h'Eireann

The following amendments to the By-laws have been approved by the Central Council:

1. Wherever the words "the Union" occur in the By-laws substitute therefor the words "the Association."
2. Correct printer's error in By-law 9 (a) (i) by reading "registration" for "resignation."
- 2A. Add Clause (v) to same By-law: Any member who holds an appointment as a commissioned medical officer in the Defence Forces of Eire shall pay an annual subscription of £2 2s.
3. To alter By-law 18 (a) permitting that a member having registered under a particular special Group shall remain a member of that Group until notification is received from such member, under his or her signature, of a wish either to resign from such Group or to transfer to some other Group. This will obviate the necessity at present existing of sending out these Group Forms annually.
4. To alter By-law 18 (d) so as to permit of Group Meetings being summoned by the President of the Union, the Chairman of the Group, or on the written request of any six members of the Group.
5. To redraft By-law 23 (b) as follows: Members of the Union elected by the several Branches to hold office for one year. Each Branch shall be entitled to elect one member. A Branch with more than fifty members shall be entitled to elect an additional member of Council for each additional fifty members or portion thereof, provided that such portion is not less than twenty-five. A voting paper containing the names of all candidates proposed shall be sent to every member of the Union whose subscription is not in arrears.
6. To amend By-law 23 (c) (iv) so as to give the Medical Officers of Voluntary Hospitals Group direct representation of four on the Central Council.
7. To correct misprint in word "Union" in By-law 24 (a), line 7.
8. To substitute word "appropriate" for word "proportionate" in By-law 24 (a) (v).
9. To substitute the word "three" for the word "five" in By-law 24 (c) (i).
10. To redraft paragraph two of By-law 42 to read as follows: "Each of them, the President and Vice-President, shall hold office until his successor be duly elected. Any casual vacancy in either such office may be filled by the Central Council."
11. To delete words "if any" in brackets in By-law 45.
12. To delete commas in By-law 46 (a) after words "except that" in line two and after word "September" in line three.
13. To delete the words "to report upon the duties devolving upon it or upon any scheme it may establish or propose," and substitute therefor the words "for such purposes as it thinks fit" in By-law 47.
14. To add the words "Honorary Secretary" after the words "President and Vice-President" in By-law 48.
15. To substitute the word "may" for the word "shall" in By-law 49 (a), line one, and substitute the word "consider" for the words "deal with" in line four.
16. To delete the words "by a postal vote" in By-law 49 (b) (i), line two, and substitute therefor the words "at the first meeting of the Group next following the Annual General Meeting," and delete remainder of Subsection 1.
17. To delete wording of By-law 49 (c) and substitute therefor the words "Each such Committee shall hold office until the close of the next Annual General Meeting."
18. To substitute the word "Group" for the word "Committee" in By-law 49 (d) and delete the words "of the members" in the last line, and add the word "Committee" after the word "Group" in last line.
19. To delete By-law 49 (e).

MEDICAL CERTIFICATES UNDER THE MILK
RESTRICTION ORDER

The Ministry of Food announces that the procedure under the Sale of Milk (Restriction) Order, 1941, for the issue of medical certificates authorizing the supply of additional milk to certain classes of invalids has been amended by an Order which came into force on August 27, 1941. Representations have been made to the Ministry on behalf of the medical profession that the existing procedure is inconsistent with established medical practice in that the disease or condition from which the patient suffers is divulged to the dairyman or other person into whose hands the certificate may pass. Under the amended arrangements the medical practitioner is asked to certify in item 2 of the certificate only that the patient is suffering from "a disease or condition specified in the First Schedule to the Sale of Milk (Restriction) Order." This arrangement has no bearing on the question of supplies to invalids under the new milk distribution scheme recently announced. Full information on this subject will be published shortly.

Correspondence

Group Practice or Bureaucratic Medicine?

SIR,—To the correspondence on State Medical Service (*Supplement*, August 16, p. 26) Dr. Leak contributes an interesting and valuable letter. As I have already advocated the substitution of group practice for individual practice (*Journal*, March 22, p. 458), I cannot but welcome his advocacy of the same cause, though to my mind the unit for grouping in the medical and health service is not the general practitioner, but the general practitioner together with all other "health workers" in the district—the public health officers, dentists, district nurses, midwives, social and welfare workers, and pharmacists. The group of general practitioners would form the leading body of the organization.

There is, however, a profound difference of opinion between Dr. Leak and myself as to what the function of these groups should be. He wants them to be the alternative to the State Medical Service, believing that this inevitably introduces bureaucratic control, and stamps out all personal relations between doctor and patient; and if he thinks—as do so many, notably Lieut.-Colonel Fairrie—that a State Medical Service can only be run on the lines of the Naval, Military, or Colonial Services, then he would be only too right in raising the loudest clamour of protest. All of us who are live men kick against being "bossed around" by officials and being ruled by regulations framed and issued by permanent office dwellers.

Without local groups we have the present anarchy, or will have bureaucracy. If the groups—each small area—work on their own as absolutely independent units all the faults of local government, with its separatism and parochialism, will be repeated over again. But Dr. Leak's groups of general practitioners could, instead of remaining isolated, become the units of the nationalized health service of the future. It is the pressure of events, not just the paper-consuming glutony of the bureaucrat, which compels and forces upon all manifestations of life an ever-increasing and complex measure of organization. We must not be blind to it; we cannot afford to make vain pretence of ignoring it. The clock is moving in this direction, and though we smash all the clocks in the world the process will still go on.

This is the dilemma which is very truly exercising the minds of millions in the world to-day, and the answer cannot be produced in a letter. The solution, however, undoubtedly lies in a system of relations between local and regional, regional and national, organizations. The last are concerned with broad issues of policy, the regional with the more concrete problems of organization, and the local with the living practice and execution of the demands for which the system came into being. For these demands are, in ultimate, the demands of human beings living diversely, in different places and in differing environments.

The greatest elasticity and personal responsibility must be given to the local bodies to carry out national policy. The living cells of this society can, therefore, only be relatively small associations of socially conscious and live men. And to be alive, men must be free. Free, not to do as they like, but free in the sense that they recognize themselves to be, and are recognized to be, adult responsible men. By grouping general practitioners together we shall be training bodies of men in groups with a larger social conscience than that which is fostered by individual and isolated enterprise. We shall not only be doing immediate good to the public we serve and to ourselves, but will also be preparing the way for a truly democratic national health service, and bringing with it our own contribution to the new order.—I am, etc.,

London, Aug. 19.

E. MONTUSCHI.

State or Socialized Medicine?

SIR,—Dr. E. U. MacWilliam (*Supplement*, August 23, p. 31) refers to "an association . . . whose primary object is to work for a Socialized Medical Service," and he takes it "that 'socialized' in this connexion is synonymous for 'national' or 'State.'" He is convinced, however, that the idea of a State Medical Service did not originate within the ranks of the medical profession, and he implicates "the doctrinaire politician."

As the general secretary of the Socialist Medical Association, which some nine months ago provided Dr. MacWilliam with the

"documentary evidence" which he now makes the basis of his surmises, may I be permitted to clarify a few of the points raised in his letter? Membership of the S.M.A. is restricted to members of the medical and allied professions—for example, doctors, dentists, pharmacists, nurses, and students of these professions. The association's main object is to work for a socialized medical service, free and open to all, and to secure for the people the highest possible standard of health. The association believes that poverty, malnutrition, and disease can only be effectively dealt with in a socialized community—that is, one in which production is for use and not for private profit.

Politics and State medicine are in themselves neither good nor bad, in the same way that arsenic, which kills men and spirchaetes, has no innate goodness or badness. It is the use to which things are put that determines their positive or negative value. State medicine is the system in Hitlerite Germany, where it is used to support the Fascist theories of blood and the sterilization of political and racial "undesirables." It is also the system in the Soviet Union, where its use has resulted in a phenomenal decrease in the tuberculosis and infant mortality rates. The value of State medicine, in fact, depends essentially on the political system within which it functions. "Medicine is a social system," wrote Virchow, the pathologist, "and politics is nothing else but medicine on a large scale."

"State medicine," about which we have heard so much lately, will be little if any improvement on the present system or lack of system unless, parallel with the change in medical organization, there is a marked improvement in the environment such as will provide proper food, housing, and working conditions for all. "Socialized medicine" implies both these changes, and we believe that it can be the means of preserving the life and health of millions of people, who will assuredly be suboptimally healthy and develop preventable disease if the good old system, which breeds malnutrition, illness, and war, is allowed to reign unchanged.—I am, etc.,

AUG 26.

ALECK BOURNE.

State Medical Service

SIR,—Dr. Pybus's scheme for a State Medical Service (*Supplement*, March 15, p. 29) has much to recommend it. There are three points which, after long and bitter and varied experience of medical service, seem to appear important. (1) Prevention and cure should be combined whenever possible. Therefore welfare centres and ante-natal clinics, domestic science classes, and gymnastics should form an integral part of the clinics. In fact, they should be health centres. (2) No one but the completely indigent should receive free treatment. Sickness, especially preventable sickness, should always be penalized, however nominal the penalty may be. This should be the rule, and of course there would be exceptions. (3) "Specialists" should be "debunked." A doctor's prestige should increase with his experience and skill in his own subject. The fact that his subject is an exceedingly limited one should not, *ipso facto*, increase his financial status or, necessarily, his impressiveness.—I am, etc.,

"OUTLANDER."

An Assistant Looks at General Practice

SIR,—In the discussion of any problem involving economic changes it is difficult for the individual to speak without emotional bias. Dispossession on the one hand and possession on the other are strong incentives to an advocacy of a communistic organization or the preservation of the *status quo*. Nevertheless, one must look for objective truths and try to sift "rationalization" from reason. I dare to say that dispossession is the emotional urge in my case, and I am prepared to be instructed where I may seem to err in reasoning in favour of a State Medical Service. Unless the sphere of medicine is the exclusive privilege of the rich, the present-day capitalization of general practice offers nothing to the young graduate who has just completed five or six years of a most exacting mental apprenticeship but, in the end, a long vista of repayments by instalment of capital, interest, life premiums, sickness and accident premiums, and guarantee premiums to the insurance companies. I have spent many years as assistant and also in practice on my own, and I have met many doctors whose hearts were heavy with their economic conditions,

which robbed them of moral dignity in their relationship with their patients. "You cannot call your soul your own," crystallizes the damaging effect of a system whereby hundreds or thousands of patients are "loaned" on mortgage like so much therapeutic stock.

The word "freedom" is so bandied about to-day that it is in danger of losing all meaning. Thus "freedom of enterprise" has come to mean freedom to try to get the highest possible price for an article, irrespective of its cost, by all methods which do not infringe the law. Freedom of choice of doctor means that the patient is free to choose his medical adviser or the surgeon who should operate on him. But a patient must clearly choose a doctor for reasons which are entirely divorced from his medical ability, since the patient is not in a position to judge; and this is borne out by my long experience of the ignorant criticisms, in most damaging terms, of doctors whom I knew to be of excellent worth, and of the praise, equally ignorant ("He saved my boy's life twelve times"), of doctors whom I knew to be not so good. Moreover, while two commodities may differ considerably in quality, I feel that differences of medical ability as between one general practitioner and another are not sufficiently great to make any difference to the real therapeutic welfare of the patient. If they are, it is a most damning indictment of the quality of medical training and of the degree itself.

It is often argued that if a patient "likes" a doctor he (or she) will be helped more by infusion of gentian and aqua than by the most expensive drugs. But if this is true, it means that the patient is, scientifically speaking, suffering from a neurosis, and should be in the hands of a psychologist. My conclusion is that, as a rule and in the long run, patients "like" whatever doctor they are used to, and they always get used to every doctor in the long run. Dr. Moore (*Supplement*, August 16, p. 27) appears to be unique in his absolute and unbounded freedom, which I hope he does not achieve at the cost of overworking an assistant. My experience is that the general practitioner is "free" to do just as he pleases provided he has a telephone system tied round his neck.

Dr. Leak paints a glamorous picture of the revealing nature of general practice. Yes, I have seen the tuberculous, gastric, and anaemic "actor" moving against his social background of poverty, overcrowding, and malnutrition, as I have seen the neurotics "moulded and modified" by other social conditions. Is Dr. Leak going to suggest that the waning of tuberculosis and chlorosis and rickets is due to the scientific investigations of general practitioners, the solace which they afforded, or the social crusade which they led? Or am I wrong in believing that it has something to do with an improved standard of living of the worker? Something too much is made of this doubtful acquaintance with the patient's background. Assuredly, a large number of patients are suffering from "dis-ease"; but the general practitioner is not educated, either medically or culturally, to treat the neurotic, and when the social background has done its evil work in establishing a neurosis it is time we realized that if we cannot alter the system the wretched patient at least merits the best and most sympathetic psychological treatment.

Dr. Turton quotes a most unfortunate example which merely illustrates that the panel system has an economic basis. Unfortunately we cannot escape the economic basis under any scheme in which the expenditure is derived from a separate taxation of the insured workers and not from a common general tax, as in Russia.

I have said nothing of the "ennobling and elevating" drudgery which the capable but impoverished assistant endures in his efforts to attain independence while retaining his morale. He dreams that one day he will have a practice of his own. Meanwhile he gets the "dirty end of the stick," and when he achieves his goal he lives under the shadow of commercial bondage. Finally, it is time that doctors became a little more conscious of social changes and what this war is about. If they don't, progress in the form of increasing social purpose will come in spite of them. "The rich may be robbed to benefit the poor" and vested interests will howl, but the institution of a State Medical Service is an inevitable step forward in the interests of the common weal, and medical posterity as well.

I append a pen-name, not because I lack the courage of my convictions but because one must work to live.—I am, etc.,

Glasgow, Aug. 20.

"ASSISTANT."

Insurance Practitioners and Collective Bargaining

SIR,—May I support whole-heartedly Dr. Inglis Cameron (*Supplement*, August 9, p. 20). As he rightly says, politicians and officials are "both unimpressed and unimpressible." We all know that great changes are due in the social services when the war is over, which doubtless will include or be preceded by some alterations in the medical services. Whether these take the form of increased health insurance schemes or a complete State scheme we do not yet know, but whatever the method pursued our best way to achieve our reasonable aspirations is by intensive propaganda now.

I would like to urge all general practitioners who find Members of Parliament, Ministry or other officials, or directors of health insurance companies among their patients and friends to make a personal and continued appeal to them to make absolutely clear what are our general problems and difficulties. At the same time we should all make it clear to our friends and patients—that is, the general public—what hours we are now working, what pay we are actually getting, and why we all feel that we are being treated unfairly.

Such presentation of the facts as given by Dr. F. M. Rose (*August 16, p. 28*) should always be kept in mind and should be hammered home daily.—I am, etc.,

Tazeworth-in-Arden, Aug. 18.

HOWARD F. BURTT.

A Change in the Health Insurance Contract

SIR,—In the report of the special Panel Conference (*Supplement*, August 16, p. 21) no reference is made to the fact that approved societies are not to pay benefit for the first twenty-six weeks of incapacity due to war causes. This may, actuarially, be as it should be. But the N.H.I. practitioner is not so treated. He has to attend his insured patient suffering from a war-caused injury for his basic capitation fee. No practitioner is likely to be concerned about that aspect of the matter in times like the present, but the principle whereby the societies are allowed to contract out of war-caused incapacity but the practitioner not is unjust.

The word "insurance" implies sanctity of contract, without which no insurance of any kind could be effected. The contract in this case is between the Ministry on the one hand and the societies and the practitioners on the other. If one side and half the other arrange to alter the contract it can hardly be held as equitable to the remaining half unless that half has willingly consented or is offered the same alteration. Or is the case now considered by the Ministry as free from contracts, as in reality all practitioners' contracts have been torn across by the inclusion of the £420 p.a. class?

The financial strength, and so the power for lobbying, of the societies is becoming extreme, and it is by such manoeuvres as above and by their receipts for each insured man in the Forces that this strength is being added to. One cannot help thinking that it was pressure from the societies that caused the Ministry to include the £420 class and to exclude the dependants of insured persons, as the obvious deduction from that course is that a much-needed social advance was jettisoned in order to bolster up the societies' funds.—I am, etc.,

Lincoln, Aug. 21.

S. WRAY.

State Medical Service

SIR,—In reply to Dr. R. S. Saxton (*Supplement*, August 16, p. 27), who suggests we apply to the U.S.S.R. State Medical Service for its experiences to guide us in the formation of one for ourselves, this is hardly opportune at the moment. Also, the standard of living in Russia is very low; the methods and foundations of an organization which may suit Russia might not suit Britain. So we had better leave the U.S.S.R. out of it.

In reply to Dr. E. U. MacWilliam (*August 23, p. 31*), my letter was inspired by a desire to help the civil members of my profession in their post-war difficulties. I have no "fish of my own to fry" nor assumptions nor conclusions to force on anyone. As regards Dr. MacWilliam's idea as to the origin of the proposal for a State Medical Service, I may ask: Did the Council of the British Medical Association, in setting up its Medical Planning Commission, accept instruction from or act on the propaganda of the undetailed and mysterious association referred to by Dr. MacWilliam? Was the original letter of Dr. Pybus inspired from the same source? Whatever motives prompted

the medical profession to consider the formation of a State Medical Service, the main one undoubtedly is dissatisfaction with the present medical insurance and panel system, with its administration by approved friendly societies, and in particular with the scale of remuneration for medical services rendered. I think I am correct in stating that the panel system pleases neither doctor nor patient. This certainly is a motive originating within the ranks of the medical profession.

My assumptions concerning the post-war financial position of private persons who, before the war, were able to give handsome subscriptions to civil hospitals and who were able to pay generous fees to their medical attendants, require and can have no proof, as by the nature of things they are more of a prophecy than an exact conclusion. The proof of a prophecy consists of its fulfilment; for that we must wait and see.

Questions of high finance are not suitably discussed in the columns of a medical journal, but references are justifiable as to the effect of this war on the financial position of individuals who, as patients of one kind or another, provide the medical profession—to put it baldly—with their incomes and mainly support our civil hospitals. A war costing a hundred millions a week, the end of which no man can foresee, as well as the cost of material reconstruction afterwards, will have to be met somehow and in the end by the individual. Such cannot be escaped by juggling with our monetary system, either of a sane or an insane character but certainly not simple. Proposal (a) of Dr. MacWilliam is pure communism, the fallacies of which have been exposed elsewhere. On proposal (b) I can offer no criticism, since Dr. MacWilliam does not tell us of what it consists. However, I think the introduction of this particular "simple adjustment of our monetary system"—a non-medical subject—was the main reason for his letter.—I am, etc.,

S. H. FAIRRIE,

Tunbridge Wells, Aug. 25.

Lieut.-Colonel, late R.A.M.C.

Extension of Health Insurance

SIR,—In such accounts as have been published of the negotiations in regard to the recently proposed extension of scope of national health insurance, I can find no evidence that due consideration has been paid to the unfortunate position of the general practitioner with a middle-class practice who has hitherto been able to maintain his status in the best tradition of private practice without succumbing to the indignities and injustices of the panel. Such private practitioners, by remaining outside the panel, have served the profession as a whole by being a standing witness to the dissatisfaction of the profession with the panel system as at present constituted. The extension of the scope of N.H.I. now threatened means that these doctors must either be prepared to capitulate to the system which their less fortunate colleagues are, of necessity, compelled to operate with such evident dissatisfaction, or, alternatively, must see the invasion of an important proportion of their patients' families by their panel colleagues. Have these doctors any grounds for believing that the B.M.A. has exerted itself on their behalf? I can find none. The published accounts seem to indicate that the B.M.A. and our profession's spokesmen in both Houses of Parliament, instead of resisting this extension of scope of N.H.I. at any price, have conceded the principle without demur and have confined themselves to bargaining over the few pence which are to be the price of this encroachment.

Neither can I find that due publicity has been given to the fact that the profession, through its representatives, has even attempted to mitigate the misfortune which threatens the patients concerned in this new act of the legislature by trying to secure a square deal for the panel doctors which would enable them to give a square deal to their panel patients.

I foresee that these patients are going to be seriously dissatisfied when they find themselves compelled to pay for a medical service they do not desire, which is of a character admittedly less satisfactory than that which they have hitherto been accustomed to receive and to afford, and which will be operated by doctors smarting under such a sense of injustice and frustration as cannot fail to tinge their professional outlook, however nobly they may strive to hide their chagrin.

In the absence of proper publicity in the lay press the blame for this new situation is going to be laid at the door of the profession. Press notices which have appeared not only fail to

indicate the profession's deep distrust of this change but actually imply falsely that the Minister of Health and the representatives of the profession are in accord over the new proposals. This is far from true, as can be seen in the *Supplement to the Journal* of August 16, 1941.

The public should be told clearly and immediately that the profession is most dissatisfied with the new plan; that the profession's representatives have only accepted it under duress and after strong protest and in consideration of the Minister's pledge that this is only a wartime arrangement; that the responsibility for foisting this ill-conceived scheme on an unwilling profession and on an unsuspecting section of the public is Parliament's and not the medical profession's. Only thus can the profession and the B.M.A. retain the confidence of the public and avoid being the scapegoat as well as the victim of Parliament's new venture in social legislation.—I am, etc.,

R. GORDON SIMPSON,
Chairman, North Middlesex Division, B.M.A.

Aug. 16.

Military Training of Medical Students

SIR,—In the *Journal* of August 23 the honorary secretary of the British Medical Students Association drew attention to "the recent Order of the Ministry of Labour making part-time military training compulsory for all medical students." I would like to draw the attention of my fellow medical students to a statement in the *Supplement* of June 7 (p. 73) that: "In the Schedule of Reserved Occupations as revised in April it is provided that all persons who have been admitted, or duly accepted for admission, as students by recognized medical schools shall be reserved. It is, however, a condition of their reservation that, except in the clinical years, they shall join a Senior Officer Training Corps or an Air Training Squadron, or undertake some alternative form of national service approved by the university authorities, and that their reservation is subject to periodical certification of satisfactory progress."

It is, I believe, a fact that the instructions sent by the Ministry of Labour to the universities stated that "the university might recommend the exemption from joining a S.T.C. or Air Squadron on such grounds as membership of the Home Guard, other Civil Defence Services, or clinical studies."

I quote the above in the hope that some authoritative statement might be forthcoming defining the position of students in their clinical years. For I feel that training should be done in pre-clinical years and the later years left entirely for clinical studies.—I am, etc.,

Stanford-le-Hope, Essex, Aug. 25.

M. MELVILLE CRAIG.

Ophthalmic Surgeons

SIR,—All ophthalmic surgeons should read "Yorkist's" letter in the *Optician* dated August 15. I cannot imagine anything more calculated to lead them to take simple precautions. The letter is too long to reproduce here, but briefly it condemns ophthalmic surgeons and hospital committees: (1) Who arrange private examinations for the less urgent cases for National Health Insurance companies (Voluntary Hospital Ophthalmic Clinics). (2) For employing dispensing opticians in place of sight-testing opticians, at the same time attributing most dishonourable motives to them. The whole of the letter and my reply will be reproduced in the next issue of the *Bulletin* of the Association of British Ophthalmologists.

In the meantime may I suggest that ophthalmic surgeons do some or all of the following things: (1) Establish similar clinics (Voluntary Hospital Ophthalmic Clinic) for insured patients and others of like income limits at the hospitals where they work, and so give themselves time for the really needy cases. (2) Employ only dispensing opticians for their hospital and private patients, for "there is hardly anything in the world that some man cannot make a little worse and sell a little cheaper, and the people who consider price only are this man's lawful prey" (Ruskin). (3) Join the British Medical Association and help the Ophthalmic Group. (4) Join the Association of British Ophthalmologists (88, Rodney Street, Liverpool) and tackle the problems which face us and so improve the ophthalmic work of our country.—I am, etc.,

Aug. 22.

OPHTHALMIC SURGEON, F.R.C.S

B.M.A. : Meetings of Branches and Divisions

UNITED PROVINCES BRANCH

At a clinical meeting of the United Provinces Branch, held at Lucknow on March 28, with Dr. E. T. BUCK in the chair, Dr. B. B. BHATIA showed the following cases: (1) pyrexia, continuous for about ten days, with a rash generalized all over the body, and a positive Wassermann reaction; (2) secondary syphilis; and (3) hypochromic microcytic anaemia with enlarged spleen and history of haematemesis: probably a case of splenic anaemia. Dr. B. N. SINHA demonstrated an old case of fractured patella in which excision had resulted in perfect movement of flexion and extension, and a case of swelling of the lower end of the femur of four weeks' duration, probably a case of osteogenic sarcoma. An interesting discussion followed each case.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following postgraduate courses: (1) Final F.R.C.S. comprehensive revision course, daily, 10 a.m. to 1 p.m., from September 29 to October 17. Instruction will include clinical teaching in the wards and out-patient department, x-ray and museum demonstrations, lectures, tutorials, and written papers; (2) Final F.R.C.S. practical operative surgery on the cadaver, Mondays, Thursdays, and Fridays, at 2 p.m., from October 6 onwards. Both the above courses will be given at the Royal Cancer Hospital; (3) revised course in anaesthetics, daily, September 29 to October 11, at the Radcliffe Infirmary, Oxford.

A series of lectures on "War Surgery of the Abdomen" will be given at the British Postgraduate Medical School from Monday to Friday, September 15 to 19 (both days inclusive), beginning at 10 a.m. daily. The fee for the course is £1 ls. Officers of the armed Forces will be admitted free provided they have obtained necessary leave and registered their names before the commencement of the course. Applications for admission should be addressed to the Dean of the British Postgraduate Medical School, Ducane Road, W. Further war surgery courses will be held as follows: beginning Monday, September 29, "War Medicine"; beginning Monday, October 13, "Treatment of Fractures"; beginning Monday, October 27, "War Surgery of the Chest."

UNIVERSITY OF GLASGOW.—A series of eight postgraduate meetings will be held in the Tennent Institute of Ophthalmology on Wednesdays from September 10 to October 29 at 8 p.m. The subjects of the addresses will include: postgraduate tuition in ophthalmology, the making of the ophthalmic specialist, ophthalmic practice in retrospect, the future of ophthalmic practice, pros and cons in ophthalmic therapeutics, ophthalmology in the law courts, and the problem of the nearly blind. There will be an opportunity for informal discussion.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—St. Mary (Islington) Hospital, Highgate Hill, N.: Wed., 2 p.m., Final F.R.C.S. Clinical Course. Royal National Orthopaedic Hospital, Stanmore: Sat., 2.15 p.m., Final F.R.C.S. Orthopaedic Course. London Chest Hospital, Victoria Park, E.: Tues. and Thurs., 2 p.m., M.R.C.P. Course in Chest and Heart Diseases. Brompton Hospital, S.W.: Mon. and Thurs., 5 p.m., M.R.C.P. Course in Chest Diseases. West End Hospital for Nervous Diseases: Tues. and Fri., 3.30 p.m., M.R.C.P. Course in Neurology. Royal Chest Hospital, City Road, E.C.: Wed., 3.30 p.m., M.R.C.P. Course in Heart Diseases.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—At Tennent Institute, Church Street, Glasgow, Wed., 8 p.m. Prof. A. Loewenstein: The Making of the Ophthalmic Specialist.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced: Eye (Suffolk); Kilwinning (Ayrshire). Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by September 16.

APPOINTMENTS

FORSYTH, W. W., M.B., Ch.B., Examining Factory Surgeon for the Darlington District (Durham).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

MARRIAGE

JAMES—HYMERS.—On August 2, 1941, Nicholas Ernest James, M.B., B.S., to Catherine Sinclair Hymers of Caithness. At Nottingham.

DEATH

HESSION.—On August 10, 1941, at sea, Dr. John E. Hession, late Surgeon, s.s. *Scythia*, Cunard-White Star Line.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 13 1941

GENERAL PRACTICE WITHIN A STATE MEDICAL SERVICE

MEETING OF NORTH LONDON PRACTITIONERS

A meeting of general practitioners from seven central and north London areas—namely, Hackney, Stoke Newington, Islington, Finsbury, Shoreditch, Bethnal Green, and the City of London—was held on September 2 to discuss the future of general practice in view of the drift towards a State Medical Service. The meeting was called by the Practitioners' Co-ordinating Committee, a body formed as a result of a previous meeting in Islington in June last, when a scheme of State medical service on lines acceptable to general practitioners was discussed.

At this second meeting, over which Dr. M. F. MOLONEY presided, there was an attendance of about forty. Each person attending was handed a copy of the following resolution, which at the end of the meeting was carried unanimously:

"In order to improve the medical services to the public and to provide the fullest facilities of modern medicine, preventive and curative, and in the light of recent developments, recognizing the probability of some form of State medical service, this meeting of medical men is prepared to accept such a service provided it includes the following aims:

- "1. A State medical service must take into adequate consideration the just requirements of the general practitioners of the country.
- "2. Adequate compensation should be made for existing practices.
- "3. Salaries rather than capitation fees are desired—salaries to be based on years of service and experience.
- "4. Pensions to be granted on retirement.
- "5. Daily hours of attendance to be limited and time off duty to be given each week. Annual leave granted on pay.
- "6. Refresher courses should be provided periodically and on pay.
- "7. Opportunities should be granted to general practitioners for means of obtaining specialized experience and research.
- "8. The general practitioner should have access to hospitals.
- "9. Clinics should be established as the centre for general practice.
- "10. Furthermore, it is resolved that for the success of a State medical service the general practitioner should have fair representation upon any Planning Board for the institution of such a service, and in its subsequent administration."

Criticism of "Executive Medicine"

The CHAIRMAN criticized the Insurance Acts Committee, especially for its concurrence in a scheme whereby persons with incomes up to £420 were admitted to national health insurance while dependants of present insured persons were left out. It would not be true to say that these dependants were left without provision, because in respect of them particularly there had been progressive encroachments by public health authorities upon what was formerly the general practitioner's sphere of activity. General practitioners were being pushed more and more into the background. Although they constituted the majority of doctors in active practice in this country, their representation on the Medical Planning Commission was wholly disproportionate. If the British Medical Association no longer had the confidence of general practitioners it was no reflection upon those who directed its affairs; rather was it a criticism of the apathy of the rank and file of its membership. Shortly there would be an election of the Insurance Acts Committee. He hoped that representatives would be chosen who were "not 'Yes-men,'

swayed by the 'brass hats' of executive medicine." Finally, he said that there was no intention of setting up an opposition organization to the B.M.A.

A Model Medical Centre

Dr. B. HYNES, one of the honorary secretaries of the Committee, illustrated the programme set out in the resolution by taking the case of the borough of Islington, with its population of 250,000 to 300,000. Under some such scheme Islington would be divided into twenty-five centres, each centre to be operated by ten medical men, so that every practitioner would have a list of some 1,000 or 1,100 persons. All patients would be seen either at the centre or in their own homes, not at the doctor's residence. He exhibited a model of one centre clinic—a building of two stories, the ground floor for consultation purposes and the upper floor investigational and residential. In the model there were ten small consulting rooms, one for each practitioner, with examination rooms and waiting rooms attached. A surgery of sufficient size and equipment for minor operations was included. On the upper floor was a pathological laboratory, an x-ray room, and two small observation wards, as well as private rooms for doctors and nurses. The personnel attached to such a centre would consist of ten doctors, the majority of whom would be in daily session at morning and evening surgeries, with visits in between, and others on night duty. There seemed to be no reason why eight hours a day should be exceeded by any doctor, except during epidemics. Other personnel would include a day and a night nurse, possibly a relief nurse, dispenser and laboratory attendant, clerk, and perhaps porter.

Dr. W. W. Fox followed the Chairman in criticizing the Insurance Acts Committee. The Committee should have demanded the inclusion of dependants of present insured persons, which was the policy of the British Medical Association as far back as 1929.

Drift towards State Service

Dr. P. INWALD, the other honorary secretary, said that the Committee had been formed for the sole purpose of protecting the public and the practitioner in any future scheme of medicine. It was actuated by no desire for self-aggrandisement, and was perfectly willing to stand down if a better body was formed. Conditions were pointing inexorably to social change in which the medical profession would have to accept some scheme of State service. A Gallup survey had shown that 55% of the people whose views were canvassed were in favour of such a service, and the National Union of Railwaymen had voted for it unanimously. It was commonly said that under such a service the intimate contact between practitioner and patient would be lost. He did not admit this, but if it were true, did the patient suffer? The self-esteem of the doctor might suffer, but not the patient. In the out-patient department did not patients accept without demur the services of total strangers? The real solution was to raise the standard of practitioner service so that the patient would feel safe in the hands of each and every one of them. The patient would look more and more for proficiency and less and less for bedside manner. The Medical Planning Commission was now in session investigating the condition of medicine to-day and endeavouring to provide for its future. But the personnel of that Commission did not represent general practitioners in anything like adequate proportions. The majority of its members, if they had ever had to face problems like those confronting general practitioners, had long since forgotten them.

General Discussion

After these speeches, which were all from the platform, the meeting was thrown open for a brief general discussion. In reply to one question the Chairman said that it was desired to bring about such coalescence of medical opinion in the country that if the findings of the Commission were unfavourable it would be possible for the rank and file to prevent their application. Only one speaker was opposed to the idea that State Medical Service would mean an improvement in conditions. The experience of London insurance practitioners of part-time employment by a State-aided body, the London Insurance Committee, was not encouraging. He also demurred to what was said in the resolution about hours of attendance; he thought that some rota of service would have to be worked out. He was doubtful about Dr. Inwald's statement that the out-patient did not mind which doctor treated him. Another speaker, in the employment of one of the boroughs represented, expressed sympathy with general practitioners in the matter of encroachment, and said that it distressed those in charge of municipal clinics to feel, however necessary their work, that they were filching it from the general practitioner.

The resolution set out above was then proposed by Dr. D. LENIHAN and seconded by Dr. G. W. MACKAY and carried. The Practitioners' Co-ordinating Committee was enlarged by the co-option of two representatives from each of the municipal areas represented.

Correspondence

Capitation Fee

SIR,—Every writer who has contributed to the discussion on this matter has attempted to issue, with more or less success, a clarion call to action. But apart from urging a continuance of barren conferences and futile discussions between the secretarial staff and the Ministry, no concrete suggestion has yet been put forward. The profession as a whole, indeed, is working under a great disability from which other more successful exponents of collective bargaining are free—namely, the consideration of our patient's welfare, which takes priority over every other factor. Any attempt at collective bargaining or united action which places in hazard the health and well-being of the panel patients who look to us for their medical attention would be foredoomed to failure by reason of lack of support from within: not one of us would wish the Association to pursue a policy which jeopardizes the confidence placed in us by our patients.

I am writing now to suggest a line of action to enforce an adequate increase in the capitation fee, which, while it places the Ministry of Health under crippling sanctions that must compel attention to our demands, has the double advantage that no hurt will be suffered by our patients from the medical point of view, and that control of the whole scheme is taken out of the hands of the central executive and left entirely in the charge of Branches or even Divisions of the Association. Moreover, the scheme has the further advantage of extreme simplicity. It is as follows.

A Branch or Division of the Association, or any group of insurance practitioners within a fairly wide area such as a whole county, having decided to take action to secure a local increase in the capitation fee within such area, acquaints the Ministry of its demands, at the same time giving formal notice that after a certain specified day, say, January 1, 1942, no further medical certificates will be issued to insured persons unless the demands are met. Before making the actual request to the Ministry certain preliminary steps will be taken by the executive to establish their position and to secure widespread and effective support from the whole body of insurance practitioners in the area. To each doctor on the local panel will be sent the following papers under one cover: (1) A leaflet explaining the demands to be made on the Ministry, and the steps to be taken if these demands are not met. (2) A note to be signed by the doctor and returned without delay to the local secretary, promising support of the scheme. (3) A letter of resignation from the panel, left undated, addressed, of course, to the clerk to the Insurance Committee but returned for safe keeping to the local secretary, together with

Item 2. (4) A large envelope addressed to the clerk for return of all blank panel certificates held by the doctor on January 1, 1942. (5) A second note for signature by the doctor addressed to the local secretary affirming: "I have to-day returned all my panel certificates to the Insurance Committee."

The scheme, once having been launched by the issue to all practitioners within a given area of the envelope containing the five enclosures detailed above, would automatically come into operation on the date specified unless the demands were met. If that fortunate event should supervene, then the scheme would be cancelled by a further communication from local headquarters. The actual return of the certificate books and the unequivocal assurance that they have in fact been returned are essential steps in the success of the scheme: first, because doctors' plans for united action always break down at the weakest point, which in this case will be the faint-hearted member who continues to issue certificates for fear of losing the patients; and, secondly, because the procedure furnishes the reply to all patients asking for their accustomed certificate—"All panel certificates have been recalled and I have none to issue." The certain knowledge that "the fellow round the corner" has also returned his certificates and is therefore unable to issue them is a great factor in keeping up morale during an unpleasant conflict of this kind. Professional unity would further be strengthened a week or so after the commencement of the scheme by the issue of a list of all practitioners who had returned their certificates according to plan; any names missing could be noted, and doubtless a telephone call or a friendly visit from a couple of neighbours would not fail to bring into the scheme any members who, through pressure of work or other cause, had been unable to keep up with the suggested time-table of operations.

In the unlikely event of the Minister wishing to take reprisals by withholding part of the quarterly payment, the local secretary, armed *in advance* with the signed but undated resignations from the bulk of the medical population in his district, would be in a strong position to protect his colleagues and to secure effective recognition of their demands. It would be most distinctly understood—and as assurance to that effect would be in the hands of every doctor signing the resignation paper—that in no circumstances would the collective resignations be tendered by the local secretary unless the total number of resignations was equal to at least 95% (or other agreed figure) of the medical personnel.

I warmly commend this scheme for the scrutiny of all my medical colleagues who, like myself, feel that they are not getting a fair deal from either the Minister or their own accredited representatives. It is, we are agreed, full time that matters should now be taken out of the hands of the central office, and local schemes arranged under regional rather than central control. I can conceive no scheme that would more completely cripple on the financial side the intricate mechanism of State insurance, while leaving unfettered our own medical services to our patients.

—I am, etc.,

Hayle, Cornwall, Aug. 22.

D. STANLEY-JONES.

Organization of Insurance Doctors

SIR,—The recent Panel Conference has impressed on most of us that all is not well with matters concerning national health insurance.

The composition and method of election of the Insurance Acts Committee are not satisfactory. As a standing committee of the Association the President, the Chairman of the Representative Body, the Chairman of Council, and the Treasurer are members *ex officio* of the Insurance Acts Committee. Six members are elected by the Representative Body. One member (who is not a panel practitioner) is elected by the Hospitals Committee. One member is elected by the Medical Women's Federation, one by the Society of Medical Officers of Health, and one by the Association of Local Government Medical Officers. The Chairman of the Panel Conference, who need not be a representative. Twenty-six members are elected by grouped Panel Committees.

It will be seen that out of a committee of forty-one whose duties are to deal with all matters arising under National Health Insurance Acts, twenty-six only are elected directly by panel doctors, and all have the same voting power. The twenty-six should be elected on numerical representative strength rather than on a

territorial basis. The remainder of the committee should be altered as follows: No members elected either by Representative body, or by Hospitals Committee, Medical Women's Federation, Society of Medical Officers of Health, Association of Local Government Medical Officers. Any alteration such as that proposed would have to be made by the Representative Body.

The Panel Conference as at present constituted by no means fairly represents the views of insurance doctors. At present panel Committees are represented by one representative for every 100 or part of 100 above each completed 400 panel doctors in the insurance area. It follows therefore that when a Panel Committee represents fifty doctors it will through its representation have an equal voting power with that representing 400 doctors. The injustice of this was exemplified at the recent conference at which a decision of paramount importance was decided by a vote of 98 to 79, and one was left wondering whether this really represented the views of panel practitioners as a whole. It could be argued that in practice decisions so taken do fairly represent the views of panel practitioners, and one could concede this in the case of an overwhelming majority.

It is obvious that for reasons of economy one could not take the smallest Insurance area in the country and make this the unit of representation and increase the representation in other areas in proportion. The only other alternative is a card vote based on this unit of representation. Until this desirable objective is reached no decision involving a change of policy should be accepted unless it is backed by a two-thirds majority of representatives present and voting. The chairman of the conference should be a representative. This would bring the conference into line with the Annual Representative Meeting.

There were other points of secondary importance which were apparent at the recent conference. The Agenda Committee (one assumes that it met) should have grouped the various motions so as to make it possible for the chairman and representatives to understand their relation to each other.

It is of the greatest importance that the Insurance Acts Committee should obtain without delay the written promise of the Minister that he will make no alterations in the provisions of the Act without previous consultation with the Insurance Acts Committee, and that this shall be binding upon his successors.—I am, etc.,

Birmingham, Aug. 15.

ARTHUR BEAUCHAMP.

Doctors at First-aid Posts

SIR,—Regarding the recommendations of the Select Committee on National Expenditure and the Central Medical War Committee's reply (*Supplement*, August 30, p. 33), certain comments, from experience, may be permitted. There can be no doubt that the conditions between the vulnerable and non-vulnerable areas differ. The primary need for the appointment of doctors was to carry out medical or surgical treatment in connexion with casualties. There is no justification for the payment of an annual fee in non-vulnerable areas, and payment should be for work done. In vulnerable areas the £75 per annum should be paid as a retaining fee for work done, but there is no necessity for the doctor to have any administrative power nor to have any work of training. The administrative work should be the duty of the A.R.P. medical officer, as the supervision of training can in most cases be left to the B.R.C. or St. John officers at the posts or to lay superintendents. Many general practitioners are quite unsuited to administration, and others would have been better never to have been appointed owing to their temperaments and inability to give fair treatment to the staff. The retention of some should be reviewed. Under these actual conditions there would be no necessity for medical officers in charge of first-aid posts to put in routine visits at all. If the Select Committee and the Central Medical War Committee would agree to this, then they can safely leave the training and administration to the A.R.P. medical officer, who should be the commandant of the F.A. posts. It is time that the true functions of the A.R.P. medical officer were definitely laid down by the Ministry, and that he should not be put on to school work, maternity and child welfare, tuberculosis clinics, immunization, etc., in order under the term of "A.R.P." to get a grant from the Government. He should be engaged on purely A.R.P. work and its administration, and certain powers should be definitely assigned to him to relieve medical officers of health, many of whom do not seek A.R.P.

work and in any case have enough to do. The school doctor should be kept to the school work and help the M.O.H. in public health and hospital administration. It is time the existing absurdities in administration were firmly removed by the Ministry of Health.—I am, etc.,

Aug. 31.

MEDICAL OFFICER, F.A.P.

State Medical Service

SIR,—In a letter in the *Supplement* of August 23 (p. 31) Dr. E. U. MacWilliam writes: "It may not be generally known, but it is nevertheless a fact, that there is in existence an association with many national and international non-medical affiliations, whose primary object is 'to work for a Socialized Medical Service.'" It is interesting to learn that the light of the Socialist Medical Association has at last penetrated the gloom in which Dr. MacWilliam resides. But although he appears to have heard of this association only recently, it has been well known to many doctors for the last ten years. So far as I know it has no international non-medical affiliations.

Dr. MacWilliam continues: "Though I cannot say where the 'idea of a State Medical Service originated,' I am convinced that it was not within the ranks of the medical profession." And here, I think, he is probably right. The idea of a Socialist Medical Association, I think I am right in saying, first originated in the mind of Dr. Charles Brook, and the association was founded at a meeting of doctors in London at which I was present. I suspect, however, that the idea of a State Medical Service first originated in the mind of Moses when he propounded those admirable sanitary laws that are attributed to him. It has certainly been in the minds of pioneers of health reform, both within and outside the profession, ever since.—I am, etc.,

SOMERVILLE HASTINGS,
President, Socialist Medical Association.

London, Aug. 27.

"Pure Despotism"

SIR,—I was greatly interested in Dr. T. T. Apsimon's letter (*Supplement*, August 30, p. 37). He finds that the treatment of panel doctors under the N.H.I. is not "pure despotism." He has been lucky. Perhaps my own experience may be of some interest.

In 1931 I received a notice that the Regional Medical Officer proposed to call on me on a certain date on the subject of "excessive prescribing." As I had arranged to be on holiday on that date, I wrote to him regretting that I could not meet him and informing him of the date of my return. I returned to work on a certain Monday, and at 10 a.m. on that date the Regional M.O. was on my doorstep. I protested; but my protest was waived aside on the ground that there was nothing in the regulations against it. Thus neatly and legally I was deprived of the advantage of the presence of a member of the Panel Committee. As was to be expected, proceedings were instituted in due course and a smart fine was imposed.

I urged the above circumstances as a reason for some slight mitigation of the comparatively heavy fine, but the Ministry found themselves utterly unable to see any injustice in the proceedings, and to mark the occasion the usual reduction of the fine between the recommendation of the Panel Committee and the decision of the Ministry was omitted in my case.

No one is a competent judge in his own case, but I have always felt that the nearest analogy is that of the pickpocket who relieves you of your note-case—one may admire the dexterity without necessarily condoning the offence.—I am, etc.,

Aug. 31.

JOHN H. TRENCH.

Equipment of Air-raid "Incident" Doctors

SIR,—I have received several inquiries on the equipment which I issue to "incident" doctors. The outfit is as follows: (1) A large haversack; (2) a torch; (3) wool, lint, a towel, and bandages; (4) a tourniquet; (5) scalpel, Spencer-Wells forceps, and scissors; (6) iodine; (7) morphine and syringe; (8) chloroform and anaesthetic mask; (9) funnel and rubber tube with teat at one end of tube. The object of the last item of equipment is to enable doctors at incidents to pass liquid nourishment down to trapped cases when this is possible and desirable.—I am, etc.,

GEORGE C. F. ROE,
Medical Officer of Health, Halifax.

Aug. 25.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

Surgeon Commander A. C. Paterson has been placed on the retired list with rank of Surgeon Captain.
Surgeon Lieut.-Commander W. M. Greer to be Surgeon Commander.
Surgeon Lieut.-Commander F. W. Besley, retired, to be Surgeon Commander, retired.
Surgeon Lieut. M. G. H. Hough to be Surgeon Lieut.-Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Acting Surgeon Lieut.-Commander H. J. Wade to be Surgeon Lieut.-Commander.

Probationary Temporary Surgeon Lieuts. C. E. Brownridge, J. F. Burdon, K. D. Young, J. G. Byrne, D. A. Miln, D. R. Kilgour, J. D. Kidd, K. C. Balfour, A. G. G. Long, J. McL. Lees, E. B. Grogono, J. H. D. Taylor, C. D. Falconer, I. S. Bergius, E. E. Jones, J. C. Angell, E. G. McInosh, J. S. Hogg, R. Taylor, H. D. Ross, C. Fraser, R. C. Percival, S. W. Maxwell, J. C. Ryle, J. Young, W. E. Roden, D. A. Parker, A. Mathison, M. G. McColl, A. M. McCall, H. King, A. M. Evans, T. H. Tweddy, and A. McN. McKelvie to be Temporary Surgeon Lieutenants.

Probationary Temporary Surgeon Lieut. (D.) W. Hughes, M.R.C.S., L.R.C.P., to be Temporary Surgeon Lieut. (D.).

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel R. G. Martyn has retired and remains employed.
Major (temporary Lieut.-Colonel) W. Bruce, O.B.E., to be Lieut.-Colonel.
Captains (temporary Majors) T. M. R. Ahern, R. Johnston, and J. B. MacFarlane to be Majors.

Short Service Commission.—The appointment of Lieut. J. A. Farrell has been antedated to February 1, 1938, under the provisions of Article 39, Royal Warrant for Pay and Promotion, 1940, but not to carry pay and allowances prior to February 1, 1939. Lieut. J. A. Farrell to be Captain.

Lieut. C. D. Cruickshank to be Captain.
Lieut. A. W. Douglas has relinquished his commission.
To be medical officers with relative rank of Lieutenants: Helen S. Jackson, Phyllis D. Leslie, Frances B. C. Livingston, Beatrice L. H. Sergeant, Mercy S. Cam, Grace A. Johnson, Elizabeth J. B. Orr.

MILITIA

ROYAL ARMY MEDICAL CORPS

Major F. H. B. Norrie, O.B.E., having attained the age limit, has relinquished his commission, and retains the rank of Major.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

The notification for September 14, 1939, regarding Captain (now Temporary Major) C. S. Swinburne in a *Supplement to the London Gazette* dated August 1, 1941, is cancelled.

Second Lieut. (War Substantive Lieutenant) H. E. D. Flack, from R.A. (T.A.), to be Lieutenant.

Superannuary for service with Durham University (Medical Unit) Training Corps (Senior Training Corps): C. H. Tonge to be Lieutenant.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Captains W. F. G. Scott and C. W. Aikman have relinquished their commissions on account of ill-health.

Lieut. (unpaid) acting Major (unpaid) J. R. Murray has relinquished his commission.

Lieuts. B. A. Janney, P. E. Sundt, J. T. M. Fenton-Fyffe, and K. W. Vandy have relinquished their commissions on account of ill-health.

In the *Supplement* of August 23 (p. 32) the initials of Lieut. R. W. P. Johnson were wrongly given and the surname of Lieut. B. P. Tully was misspelt.

To be Lieuts.: H. Burt-White, E. Egan, J. Anderson, W. Auld, A. Berkeley, H. A. Brittain, J. S. Burns, S. Campbell, P. T. Chopping, D. M. Douglas, B. Fairbairn, S. T. Falla, J. Frankenthal, J. Gilmore, W. Gregor, F. C. R. Harvey, J. C. Houston, W. B. Howell, J. R. S. Innes, W. Ironside, D. Kay, J. Lawrence, R. C. Le Masle, G. Levy, D. Lewis, C. Low, J. S. McCrae, P. F. Meyer, P. F. Milling, W. H. P. Minto, L. C. Montgomery, J. D. Muir, I. S. D. Ritchie, H. D. H. Robinson, W. J. Y. Speedy, B. E. C. Stanley, J. S. D. Thomson, J. V. Todd, J. Wallace, W. K. J. Walls, P. Wardlaw.

ROYAL AIR FORCE

Flight Lieut. F. V. MacLaine has been granted a permanent commission in the substantive rank of Flight Lieutenant.

Miss Kathleen E. Byrt has been promoted to the relative rank of Flight Lieutenant (War Substantive).

ROYAL AIR FORCE VOLUNTEER RESERVE

D. M. Meekison to be Squadron Leader.
To be Flight Lieutenants: D. N. Matthews, F. D. M. Livingstone, B. G. Parsons-Smith, C. E. W. Wheaton.

Flying Officers F. S. Rae, W. N. Watt, W. E. Bryan, P. A. Tyser, R. G. S. Grant, J. H. McIlraith, E. J. Blair, J. D. Jenkins, C. A. I. Fuge, C. A. Dowding, T. R. Davison, G. G. Hartill, R. F. T. Finn, C. V. Gledhill, J. F. Bohn, J. D. Thomson, A. G. Riddell, J. W. Paulty, R. R. Klein, W. F. Tierney, W. T. Gordon, A. Hargreaves, W. B. Waterfall, C. H. George, M. N. Phillips, J. M. Sward, V. E. A. Marwood, E. P. S. Snell, R. D. Kennedy, and A. W. Woodruff to be Flight Lieutenants (War Substantive).

Flying Officer J. Burdon-Cooper has relinquished his commission on account of ill-health.

To be Flying Officers: A. L. Alban, C. Bucknall, J. L. Coleman, R. G. Denniss, J. C. Garland, W. A. Glen, H. Goulden, S. Gruber, H. E. W. Hardenberg, F. S. Jackson, E. Jones, N. W. R. Lucas, J. B. H. McArthur, F. E. Massie, M. J. O'Donnell, E. T. O'Sullivan, D. C. Rawlings, H. V. Reeves, H. L. Roxburgh, E. S. Samuels, G. W. E. Studley, A. M. Abrahams, A. G. Beattie, F. V. A. Bosc, R. H. Evans, W. Flynn, R. C. Fuller, T. Hardy, H. N. G. Hudson, M. H. Kilmorth, G. A. D. Lamb, F. W. Laurie, J. K. McCabe, A. E. Macdonald, A. D. Maclean, K. S. Mullard, W. E. Scott, R. H. Armin, R. Boggan, N. T. Brown, O. T. Brown, A. C. Camm, C. M. Carr, J. M. Duncan, M. D. L. Finlay, J. J. Glynn, W. L. Hardman, J. W. Jackson, J. S. Lane, P. A. Maughan, J. F. S. McKee, R. E. McLachlan, D. G. MacNeill, W. M. Morgan, A. de W. Ranken, T. W. Robson, H. R. Rollin, W. H. T. Shepherd, A. R. Silcock, C. A. N. Anderson, W. D. Arthur, G. N. Blackburn, R. J. Gampell, R. B. Clayton, L. Clement, W. E. Coates, R. E. Dunn, C. M. Gregory, G. Hale, P. M. Peters, O. Plowright, W. L. Price, W. Sewell, G. C. Smith, H. A. Wilson, R. B. Wyde.

DENTAL BRANCH

W. O. Baird, M.R.C.P., L.R.C.P., to be Flying Officer.
Flight Lieut. J. L. Trainer, L.R.C.P.&S.Ed., has been transferred to the Medical Branch in his present rank and seniority.
Flying Officer J. W. S. Harvey, M.R.C.S., L.R.C.P., to be Flight Lieutenant (War Substantive).

INDIAN MEDICAL SERVICE

Colonel D. F. G. Murphy, M.C., has retired from the Service.
Lieut.-Colonels H. S. Cormack, M.C., and J. H. Hislop, M.C., have retired from the Service.

Major R. McRoberts to be Lieut.-Colonel.
E. J. Crowe to be Captain.
Lieut. F. Murray has relinquished his commission on account of ill-health.
To be Lieutenants: P. A. L. Roberts, J. A. MacM. Beaton, M. B. Klein, E. G. W. Lynch, and A. D. Wilson.
The name of E. Dunsby is as now described and not as stated in the *London Gazette* dated July 11, 1941.

ARMY IN BURMA RESERVE OF OFFICERS

EMERGENCY COMMISSIONS

To be Majors: C. Strickland and G. L. Talwar.
To be Lieutenants: A. Banerjee and P. K. Banerjee.

COLONIAL MEDICAL SERVICE

The following appointments are announced: C. Bowesman, M.D., F.R.C.S., Medical Officer, Gold Coast; Minnie Gosden, M.B., B.S., Pathologist, Sierra Leone; K. H. Utley, B.Ch., Senior Medical Officer, Hong Kong; E. A. Blok, L.R.C.P.&S.Ed., Assistant Director of Medical Services, Ceylon; J. D. Reid, M.B., Ch.B., D.P.H., Medical Officer, Sierra Leone.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following postgraduate courses: (1) Final F.R.C.S. comprehensive revision course, daily, 10 a.m. to 1 p.m., from September 29 to October 17; (2) Final F.R.C.S. practical operative surgery course on the cadaver, Mondays, Wednesdays, and Fridays, at 2 p.m., from October 6 to 31. Both the above courses will be given at the Royal Cancer Hospital; (3) Final F.R.C.S. course in urology, Thursdays, 2.30 p.m., September 25 to October 16, at Colindale Hospital; (4) revision course in anaesthetics, daily, September 29 to October 11, at the Radcliffe Infirmary, Oxford.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE	Road, W.—Daily,
10 a.m. to 4 p.m.,	Clinics and Operations.
Obstetrical an	Mon., Course on
Daily, 1.30 p.m., Post	War Surgery of Abdomen commences. Tues., 11 a.m., Paediatric
Clinic, Dr. R. Ligi	Conference (Medic
R. T. Brain; 2 p	White, Fri., 12.15
2 p.m., Clinico-pat	Sterility Clinic, Mr. V. B. Green-Armytage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*St. Mary Islington Hospital*, Highgate Hill, N.: Wed., 2 p.m., Final F.R.C.S. Clinical Course. *Royal National Orthopaedic Hospital*, Stanmore: Sat., 2.15 p.m., Final F.R.C.S. Orthopaedic Course. *London Chest Hospital*, Victoria Park, E.: Tues. and Thurs., 2 p.m., M.R.C.P. Course in Chest and Heart Diseases. *Brompton Hospital*, S.W.: Mon. and Thurs., 5 p.m., M.R.C.P. Course in Chest Diseases. *West End Hospital for Nervous Diseases*: Tues. and Fri., 3.30 p.m., M.R.C.P. Course in Neurology. *Royal Chest Hospital*, City Road, E.C.: Wed., 3.30 p.m., M.R.C.P. Course in Heart Diseases.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—At Tennent Institute, Church Street, Glasgow, Wed., 8 p.m. Dr. John Marshall: The Problem of the Partially Blind.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTH

ROSS.—On August 30, 1941, to Betty, wife of Major K. M. Ross, R.A.M.C., of Farnham, a son.

DEATH

BURGESS.—On August 31, 1941, at Ashlea, Cheadle, Cheshire, Elspeth, beloved wife of Arthur H. Burgess, F.R.C.S.

COURSE FOR HOME GUARD MEDICAL OFFICERS

There were approximately 150 applications for the course for Home Guard medical officers, arranged for September 11 to September 16 at St. John's College, Cambridge. The course was limited to 40, with the inevitable result that the majority of applicants have been unsuccessful. The successful as well as the unsuccessful applicants have now been communicated with. It is hoped that it may be possible to hold a further course in a few months' time, and to give preference for such a course to the unsuccessful applicants for this course.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 20 1941

British Medical Association CONFERENCE OF REPRESENTATIVES OF HOME DIVISIONS

A Conference of representatives of Home Divisions of the British Medical Association was held in the Great Hall of the British Medical Association House, London, beginning at noon on Thursday, September 11, and continuing until the late afternoon of the following day. Almost all the Divisions in Great Britain, as well as the Northern Ireland Branch, were represented. On the motion of Mr. H. S. SOUTTAR (Chairman of the Association's Council), Dr. H. G. DAIN (Chairman of the Representative Body) was unanimously elected to the chair, and he was supported by Mr. Souttar, Dr. T. Fraser (President), Dr. J. W. Bone (Treasurer), and Dr. Peter Macdonald (Deputy Chairman of the Representative Body).

The Conference was summoned by the Council of the Association to consider problems of current medical interest. Its first business was to discuss the Council's Annual Report (*Supplement*, May 17), together with a later statement on "Recent B.M.A. Activities" (*Supplement*, August 30), but time was afforded for the discussion of problems raised by Divisions, whether referred to in these documents or not. There were on the agenda sixty motions sent forward by Divisions.

FIRST DAY

Statement by Chairman of Council

Mr. H. S. SOUTTAR, in a statement to the Conference, said that the normal activities of the Association had, of course, been gravely interrupted by the war. As an Association they were making a very great contribution towards the successful prosecution of the war effort. He grieved to say that no fewer than sixty-two members had already sacrificed their lives in the cause of their country. The roll of honours and distinctions gained on service was already lengthy. At home the Association buildings had sustained damage, and only the promptitude of members of the staff on more than one occasion had saved them from destruction. The *British Medical Journal* had continued to give full service, and here he desired to pay a tribute to Colonel R. G. Gordon, chairman of the Journal Board, the members of the Board, and the editorial staff for carrying on the *Journal* under very difficult conditions, including the destruction by enemy action of the premises at which it was formerly printed.

The Central Medical War Committee was relied upon by the Government for the supply of medical men for the Forces, and it was engaged to supply further large numbers. It was essential that members should realize what immense commitments had to be met. The work was carried out in closest co-operation with the Services, Government Departments, and the Royal Colleges. Complaints were often forthcoming that no adequate use was made of medical men who were taken from civil practice for the Forces, but he could assure the Conference that although it was impossible to avoid some wastage of effort, the demands of the Army, Navy, and Air Force were reasonable and must so far as possible be met.

Mr. Souttar then went on to speak of the Medical Planning Commission. This Commission had been formed, he said, not as fully representing every body that might have a claim to be represented, but as the best group of men that could be got

together at the time to advise the medical profession on matters affecting its future. After much negotiation the close co-operation of the three Royal Colleges had been secured, and he thought it could now be claimed that the Commission represented the whole of the medical profession. It had been divided up into certain committees, including a General Practice Committee, which in his view was fundamental to its entire work, and other committees dealing with special practice, public health, teaching hospitals, etc., and there was also a Co-ordinating Committee. The Commission was aiming to produce a post-war plan for consideration by the profession, and in doing so desired to carry the whole profession with it. When the scheme had been reduced to some tangible form it would be submitted to every Division for its criticisms, and also to the Royal Colleges and other bodies. It was hoped that a scheme would be worked out which would command the complete support of the medical profession throughout the country. He ended his remarks by saying how much the Association owed to the work of its permanent officials during this difficult period. (Applause.)

Medical Planning

Dr. F. DALLIMORE (Stockport) moved:

That in the opinion of this meeting the individual member of the public and the doctor of his choice still constitute the primary essential element in the health service of this country, and that the Medical Planning Commission be invited to express its acceptance of this principle.

He said that in a memorandum recently issued by the Ministry of Health and circulated among medical officers in charge of first-aid posts the Ministry insisted on all persons with open wounds being given a dose of tetanus antitoxin. No discretion was left to the doctor, and failure to administer the antitoxin might result in an action for damages. A proclamation of therapeutic measures by bureaucrats! A gesture of contempt for the intelligence of medical practitioners! A Government Department which issued so clear and full an exposition of its policy must be very sure of itself. In seeking support for its motion his Division was moved by no narrow motive. If they could be sure that every individual member of the public would continue to insist on his right to choose his own doctor, for which in return he would receive sincere and efficient service, there was good prospect of the danger of a bureaucratic medicine being averted. But if as a result of indifference or persuasion the public surrendered that right the way would be opened for intervention, and intervention would bring them well on the road to complete subordination of the profession, with results which would be disastrous for the profession, and not for the profession only. The nation would be inadequately served by a medical profession owing allegiance to an oligarchy, in which none but sycophants would be likely to survive.

Another danger lay in the chaotic condition of the health services of this country. There was a complete lack of co-ordination. Government Departments vied with each other in efforts at control of various services throughout the country. The lack of order and system involved a very serious wastage of resources, both financial and administrative. Any person or corporation that could produce out of this chaos a comprehensive, well-coordinated system of health services would deserve well of the country. In Stockport they were fearful lest the Government should step in and seize the opportunity to extend its control of medical affairs. They were hoping that somehow the initiative in this great enterprise would fall to the

lot of their own profession, and when they heard of the formation of the Medical Planning Commission they awaited eagerly for news of its plans and activities. The organization of the Commission would receive more support and less suspicion if the mass of general practitioners had been allowed to elect representatives for themselves. One of the first needs in any well-organized smoothly working health service was that there must be complete mutual understanding and confidence between the medical profession and the general public. In the attainment and maintenance of that happy association between doctors and public the key position was held by the general practitioner. If they were justified in their expectations that the Medical Planning Commission would undertake the task of reorganizing the health services they hoped it would give consideration to the needs of general practice, that there would be careful selection of those who entered the profession, that the medical curriculum would have as its aim the turning out of highly competent men and women, that the conditions of service would be such as to attract first-class people, and that the remuneration would be on such a scale that the general practitioner would not need to take more work than he could adequately perform.

Mr. P. W. L. CAMPS (South Middlesex) proposed, and Dr. W. A. HOLNES (Peterborough) seconded, certain verbal amendments to the resolution, which were accepted by the proposer, and the resolution was carried in the following form:

That in the opinion of this meeting the family and the family doctor of the patient's choice still constitute the primary essential unit in the health services of this country, and that the Medical Planning Commission be invited to regard this as a fundamental principle.

Dr. M. STEVENS (West Suffolk) moved a resolution urging the need for early publication of an interim report by the Commission. He said that it would be some time before the full result of its deliberations would be available, and some early report seemed to be required. A great deal of correspondence on State medicine was now appearing in the medical journals, and the fullest discussion of this vital subject by the whole rank and file of the profession at the earliest moment was desirable. The probability was that the final scheme approved by the Commission would be adopted by the Government, and therefore it was all the more necessary that an interim report should be published in order that all medical men might have an early opportunity of giving expression to their opinion. This would go far to mitigate any resentment against the final plan adopted.

Mr. SOUTTAR, speaking as Chairman of the Commission, said that its whole object was to carry the medical profession with it. No report would be issued until the members of the profession as a whole had been consulted. To issue a formal interim report without such consultation would be a very great mistake, but they must not expect the Commission to work too fast. The whole problem bristled with difficulties and was one of quite extraordinary complexity. He could promise that the members of the Association would be kept informed as to the progress of the inquiries, and that the fullest consultation would take place.

Dr. STEVENS withdrew his motion, as did Dr. L. KILROE (Preston), who had a similar motion on the agenda, in view of the statement made by the Chairman of the Commission.

Dr. C. M. STEVENSON (Cambridge) urged that the report should be available for discussion by the profession before being published at large. Mr. SOUTTAR again said that the profession would be fully informed. It would be a great mistake to publish even in their own *Journal* many of the tentative findings which the members of the Commission discussed in the most open and free manner among themselves.

Dr. STEVENSON welcomed Mr. Souttar's assurance, and in view of his statement certain other motions were withdrawn.

Dr. F. W. CHEESE (East Kent) was anxious that the findings of the Commission should be circulated in sufficient time to be considered by men away from their practices, and Mr. SOUTTAR said that this would be taken into account.

Constitution of Planning Commission

Dr. J. S. HUTCHISON (Halifax) moved a resolution supporting the principle of a Medical Planning Commission, but disapproving of the personnel and method of constitution of the

present Commission. He said that the criticism which was implied in such a motion was that on so important a matter as the study of the future of medicine the Council had set up the Commission without a referendum to the Divisions. The Commission would have carried much more weight had it been elected by members of the profession as individuals. It was also the view of his constituents that the whole question of the future of medicine was being tackled from the wrong end. The answers to vast problems of this kind were apt to be over-synthesized, and many small details of great practical importance would be missed. The Council's action savoured too much of the formula "a marriage has been arranged." It rather suggested Hitler's "plebiscites."

Dr. R. BOYD (Manchester) said that the Commission was composed for the most part of "yes-men." It would formulate a plan and present it to the Divisions as something cut and dried, and whatever the nature of the plan they might be pretty sure that the general practitioner would still remain, as in the past, a hewer of wood and drawer of water. It was up to that meeting to show the Council that they were entirely dissatisfied with that method of arrangement.

Mr. SOUTTAR said that no one was more strongly in favour of democratic methods than himself, but here they were faced with a complicated and difficult problem. One might just as well send out a questionnaire to the medical profession on the differential calculus as on a matter of this kind. As for the representation of different points of view on the Commission, at its very first meeting some of them feared that the whole thing might break up in a riot, so diverse were the points of view expressed, but he was glad to say that they were gradually working together as a homogeneous whole.

On a show of hands the Halifax motion was carried by 68 votes against 54.

Dr. HUTCHISON further moved on behalf of Halifax that no further changes should be made in the conditions of medical practice until opportunity had been given for full discussion by all members of the profession. Recently, he said, they had been faced with an increase in the income limit as applied to persons under national health insurance, and there was a general feeling throughout the profession that this increase had been thrust upon them without an opportunity of discussion. There was too much of a tendency to arrange things for the profession.

Mr. H. J. MCCURRICH (Brighton) supported the motion. At present, he said, the bulk of the medical profession were too busily engaged in winning the war to deal adequately with what might happen after it, and they might find that while they had been so engaged, conditions had been changed for them.

The motion was carried.

Espying "Strangers"

Dr. A. V. CAMPBELL (North Staffordshire) moved to express the opinion that representatives of the Ministries of Health and of Labour should be excluded from meetings of the Planning Commission until the ultimate meeting of the Commission at which its findings would be discussed. His objection was that if these representatives were present at all the discussions it gave them an opportunity to find out the weak spots in the profession and might possibly help them to formulate some future opposition in circumstances which might imaginably arise.

Sir KAYE LE FLEMING said that he had been a little disappointed on listening from the floor of the house to the arguments put forward that afternoon. He was disappointed, in the first place, because recognition did not seem to have been given to the Association for its foresight. The Association at this early stage was the only body to foresee that great changes must come about as the result of the war, and it had tried to take some practical step to ensure that those changes should not be disadvantageous to medical practice. He thought it was a long-sighted policy and that the Association was to be congratulated on having formulated it. If the Commission was to do any good it had to study every section of medical practice from every point of view. It had to listen with an open mind to those who advocated this, that, or the other form of change, and only when it had

finished its hearing would it be in a position to put before the medical profession the issues which had been raised, and which the profession—not the Commission—must determine. If there were going to be important changes in medical practice after the war, which would they prefer—that the Ministry of Health and the other Ministries should themselves decide what those changes should be, or that they should be decided by those who had a full knowledge of the opinion of the profession at large? It was a most important thing that representatives of the Departments concerned should be able to listen to views from every side of the profession, because they would naturally wish, in bringing forward legislation, to meet the general trend of professional opinion.

Dr. CAMPBELL said that in bringing forward the motion it was not intended to suggest that representatives of the Ministries should not give evidence, but only that they should not be present to listen to all the discussions.

The resolution was declared carried by 68 votes against 65.

Mr. SOUTTAR said that the Conference had already light-heartedly passed a resolution denouncing the constitution of the Commission, and now it had denounced one of the most vital parts of the Commission. He fully understood that it had done both these things in complete ignorance of the extreme difficulties under which the Commission had been constituted at all and of the very great importance of the Commission working in the closest possible co-operation with Government Departments. The representatives of the Ministry of Health and the Ministry of Labour were of the greatest possible help to them. ("Hear, hear.")

Mr. BISHOP HARMAN asked whether the motion just passed was a vote of censure on the Council. If that were so the next business would be the Council's resignation. Did representatives wish that to happen? ("No.") The Council was in favour of proceeding with the Commission, it had most carefully considered its personnel, and now the Conference was implying that in asking the representatives of Government Departments to come and give information and work with them the Council had done the wrong thing. These two resolutions if acted on would be disastrous. He suggested that they both be referred to the Council.

Request to the Commission to Continue its Work

The CHAIRMAN said that a motion had been handed in, duly proposed and seconded, that, despite the passage of the resolution disapproving of the personnel and method of constitution of the Commission and the further resolution that representatives of the Ministries of Health and Labour be excluded from all meetings of the Commission until the ultimate meeting, "This Conference desires the Medical Planning Commission to continue its work with its present personnel and procedure, on the understanding that no decisions are reached or announced until considered by the Divisions and by a Representative Meeting."

Dr. S. WARD (Birmingham), in moving the above resolution, said that he had always advocated in the Representative Body and in the Divisions that, above all, the profession must be prepared in advance for even unlikely eventualities. The Council in this case had taken steps to do something which would make the profession fully prepared, and had done so under conditions of the greatest difficulty. Many of them who were on the Council had disagreed with the way in which the personnel was put on the Commission, but they had to admit that whatever method was adopted, unless it made the Commission into a parliament of six hundred, there would be complaints at least equal to and probably greater than those voiced at the Conference. It was necessary to face up to the fact that whatever the Council had done in its selection of personnel there would have been serious complaints. One complaint of another kind that had been made in the past was that they had failed to get their point of view across to the appropriate authority, such as the officials in the Ministries. But they could never get them around a table to hear the discussions which led up to their findings. Such a table had now been furnished in the shape of the Commission, and there the officials could learn not only of the findings but of what had led to them. They had nothing to hide in their discussions, and they would be glad to have these officials present. A resolution had been passed that afternoon

deprecating the fact that for the first time they had been able to do what they had always aimed at doing. He had not intervened earlier in the discussion because he felt that as a member of the Council and a member of the Commission it might be thought that he was trying unduly to influence the Conference. After the resolution which had been passed some of them would have to consider very carefully whether they had a right to sit on the Commission. If the British Medical Association withdrew its support from the Commission very great difficulties would arise and the profession would be left high and dry, for, whatever they might say, the British Medical Association offered the most representative and most thoughtful body of all those which were attempting to look after the interests of the medical profession. Never in his medico-political career had he been called a "yes-man," and he could assure them that on the Commission there was an open mind to receive, to hear, to arrive at the facts, and then to collaborate and produce something of which at the end of the war the profession would be proud. (Applause.)

Colonel R. G. GORDON desired to say a few words from the point of view of the Services. Service members had expressed dissatisfaction with the Medical Planning Commission, and at a largish meeting at a military hospital a resolution of disapproval, was passed unanimously. He had therefore thought it his duty to try to find out exactly what was the ground of this disapproval and what steps could be taken to remedy the situation. Many of the medical officers complained that they were not represented. That was perfectly true, and that was the difficulty of the situation which had arisen that afternoon. So many people said they were not represented, and yet if account were taken of the composition of the Commission a very wide representation of interests would be found. Furthermore, the people who were on this Commission were on the whole people who had thought about the things which it had got to do. If any of those present had attended the first meeting of the Commission they would not have thought that these were people who had minds ready made up, for a more remarkable dissonance of opinion he had never heard. This was largely a fact-finding Commission. He had found almost universal agreement with the proposition—to put it at its lowest value—that the Commission was better than nothing. If the Conference turned this Commission down, what were they going to do? They would impress the Government Departments with the idea that the medical profession was not capable of making up its mind as to what it wanted. That would be a disastrous step, especially unfortunate at a time when most of the Departments had been persuaded to come and consult the Association in preference to any other body as representing the medical profession. The Association had become established as the mouthpiece of the profession. Did the Conference want to upset all that as it would be upset if by any action of theirs they caused the Commission to disband?

Dr. J. S. HUTCHISON (Halifax) said that the motion by his Division which the Conference had passed actually supported the principle of a Medical Planning Commission. It disapproved only of the personnel and method of constitution. Their objection was that the Commission was foisted upon the profession without consultation. His Division wanted a Commission. It might on certain conditions be satisfied with the present one, and he wanted particularly to draw attention to a later motion on the agenda in his name recommending Divisions to organize discussion groups to consider the future of medicine, the results of these deliberations to be forwarded to the central body. He wanted as many members of the profession as possible to share in the responsibility of solving this problem.

Sir KAYE LE FLEMING said that he was not a member of the Commission, but no man in that Conference had more deeply at heart the welfare of the Association. The Conference had passed two resolutions, certainly by very narrow majorities, and in a sense conflicting resolutions, which had placed the Council and those of its members who served on the Commission in an extremely difficult situation. He wanted the Conference to consider the position from a much higher standpoint. If it went forth from a meeting of that kind that the action of the Council was condemned and that the Commission was disapproved, the prestige of the Association would be thrown back for years. ("Hear, hear.") It was a most lamentable position. He asked

the Conference to support the resolution now before it which offered a way out of the difficulty. Let the Commission be allowed to go on with their tacit approval until the matter could be brought forward at a proper Representative Meeting next year, and then, when they had more knowledge before them and had more time to consider resolutions, they would arrive at a proper decision.

Dr. A. W. WESTON (Dudley) said that although the Association had sponsored the Commission it must not be inferred that every member of it was necessarily a member of the Association. The members were not chosen for that reason. He was all for improvements in medical practice, and he thought it would be a backward step if, having formed the Commission, it was now allowed to lapse.

Dr. O. C. CARTER (Bournemouth) supported the motion, adding that it would be quite impossible for any member of the Commission to be there in the capacity of a representative; it would tie his hands unduly.

Dr. A. V. CAMPBELL (North Staffs) considered that the motion now brought forward was a direct negative to the one he had proposed and which the Conference had passed. If they were in a dilemma it was because the Commission had been formed without consultation with the Divisions. There were no more loyal supporters of the Association than members in North Staffordshire; nevertheless they were entitled to make their criticisms and express their opinions.

Dr. C. I. SCHIFF (City of London) said that by passing the motions from North Staffordshire and Halifax the Conference had committed itself to a wholesale condemnation of the Commission. Then the Chairman of Council had pointed out what a serious step had been taken, and the Conference got into a panic and was now going to the other extreme. He thought there was no reason why a resolution should not be passed approving of the general principle of a Commission and in great part of the constitution and method of working of the Commission now set up, but suggesting that some alterations might be made. If the motion now before the Conference was defeated he would be prepared to move another which would offer a *via media*.

Dr. R. BOYD (Manchester) said that if the Conference passed this motion, which was a direct negative to the motion by Halifax, it would stultify itself.

Dr. E. A. GREGG spoke in support of the motion, and said that those who had consistently criticized the Association for failing to be on the spot in time could no longer do so. The setting up of this Commission was a stroke of genius. Had the Association not stepped in and done this, other interests would have done so very quickly. Any action which would tend to take away from the confidence felt by the profession in this Commission would be fatal. If the Commission were in any way to suffer as the result of some slight cast upon it by that Conference, some other body would take the field and would get itself into the position of being accepted as more representative than those chosen by the Association.

Dr. H. S. PASMORE (Kensington) said that he was sure they were all willing to forgive the errors which had attended the formation of the Commission and to offer it their warmest support rather than to take what would be the fatuous step of breaking it up at this critical time in the history of the Association.

The CHAIRMAN (Dr. Dain), in answer to a question by Dr. DE SWIET, explained that the Commission was set up by the Council, and gave invitations to individuals and to bodies of medical men to send representatives to take part in the discussions. It was perfectly true that it was not a committee of the Association, but the Council took credit for having thought in time of setting up a Commission of such a wide character.

Dr. HOWIE WOOD (Isle of Wight) said that one of the points of criticism was that Divisions had no voice in the appointment of the Commission. If that was so would it not be possible for the Council to ask the Divisions now to approve its composition?

Dr. WAND said that to speak of foisting this Commission upon the profession was all nonsense. Let the Commission continue its deliberations. He begged that the vote on this resolution might be so emphatic that it would mean that the Association could say to the Commission, "Go to it!"

The resolution was carried by a very large majority. Out of an assembly of not far short of 200 only 14 voted against.

State Medical Service

Dr. E. H. RICHARDS (North Staffs) moved:

That in view of the strong efforts being made by certain political bodies and groups of medical practitioners to further the introduction of State service, and the possibility that these efforts may be successful, this meeting, without expressing any opinion for or against State service, suggests that the Association ought to be prepared for such an event, and should forthwith consider such essentials of administration and minimum remuneration as would be acceptable to the profession.

He asked whether the Association was ready to put a cut-and-dried scheme into the hands of the profession. It was common knowledge that certain important bodies were striving to gain acceptance for a scheme of this kind.

Major R. SCOTT STEVENSON thought it was time for someone to get up and say that a State Medical Service was not the policy of the British Medical Association. (Applause.) He had heard so frequently recently that the B.M.A. was in favour of State Medical Service that he wondered how that idea could possibly have become current. Not long ago he met an important official of the Ministry of Health who asked him whether he was coming back to London after the war, and, on his saying that he hoped to do so, remarked, "There will not be anything to come back to. We are going to change all that sort of thing." His reply was, "You, and who else?" (Laughter.) It seemed to be forgotten that the British Medical Association had a policy on this subject, which was set out in the grey book entitled, "A General Medical Service for the Nation." In that book, laid down in a first-class way, would be found the basic principles of practice to be carried on after the war. He wished that the Ministry of Health would attend to its proper business. It had been proved conclusively that the greatest single cause of ill-health in this country was not a medical cause but an economic one—namely, poverty, bad housing, malnutrition, and so forth. What did the Ministry do? It washed its hands and said, "Let us push up the income limit for admission to national health insurance." The Ministry of Health should get down to its own job—that of dealing with bad housing and the rest of the evils which made for ill-health. Only after it had shown that it could do that effectively had it any right to go to the medical profession and discuss with them a general health policy of the nation. He repeated that a State Medical Service was not a B.M.A. policy. (Applause.)

Dr. J. B. MILLER said that there were a very large number of new representatives present on that occasion who might not be familiar with what the Association had done in the past. Years ago the Association formulated a general medical service for the nation, differing in no single respect from motions that had been at various times approved at Annual Representative Meetings. A few years ago the Association appointed a new committee to revise its proposals, and the scheme it put forward was accepted unanimously, save for one particular paragraph, by the Annual Representative Meeting of 1938. The policy so affirmed was still the policy of the Association. It was welcomed as such by the Press, by the representatives of local authorities, and by the country generally; but, of course, little public interest had been taken in it owing to the European situation which developed in 1938 and led up to the present war. A false impression had got round that in some way the Association was receding from the position it had always taken up with regard to general medical service. The policy announced in the grey book remained the policy of the Association until it was changed by a Representative Meeting. He reminded the Conference that at the end of the war of 1914-18 they were told that there would be a State Medical Service, but for 22 years since then general practice had been carried on, with gradual improvement in the conditions of the general practitioner, without a State Service. It could not be foreseen what would happen after this war, but to suggest that the Association was not prepared with a scheme alternative to a State Medical Service was quite wrong.

Dr. H. W. POOLER (Chesterfield) thought that the motion ought to be accepted. It implied some condemnation of State Service, or at any rate no satisfaction at the prospect of such a service. But it did embody a warning that sooner or later proposals for a service would be made. Surely they ought to be prepared for any attack of that nature which might be made upon them. He believed that opinion in favour of a State Medical

Service had been gaining ground in the profession, and whether they agreed with it or not they ought to recognize it. He had made a personal inquiry among the members of the profession in his own county of Derbyshire, and the results were somewhat disturbing. Of the practitioners left in Derbyshire 63% were in favour of a State Medical Service. Among general practitioners the proportion was over 50%, and among the practitioners aged from 25 to 45, 70% were in favour. He hoped that this resolution would go through in order that the Commission might consider ways and means of giving effect to what it suggested.

Mr. H. J. McCURRICH (Brighton) opposed the motion. If it were passed it would soon get about that the Association was considering a State Medical Service, and then "the cat will be among the canaries."

Dr. RICHARDS said that his reason for bringing forward the motion was in order that they might know where the Association stood.

The motion was lost.

Ophthalmic Benefit

Mr. H. J. McCURRICH (Brighton) moved:

That this meeting is of opinion that the inclusion of non-insured persons and dependants with incomes between £250 and £420 per annum, as recommended by the Ophthalmic Group Committee for treatment under the National Eye Service, would create an unwarranted restriction on private practice; and that it would form an unfavourable precedent to future extension of specialist services.

He said that this was an extension of service which was being foisted on the profession without the Divisions having had any chance of discussing it at all. Was it to be imagined that a man earning £420 a year could not afford to pay a consulting fee perhaps once in three or four years?

Mr. BISHOP HARMAN said that the Ophthalmic Group Committee considered that two facts should be recognized—namely, that the income limit for insurance entrants had been raised to £420, and that the cost of practice had increased considerably. Practitioners to the number of 870 on the Association's ophthalmic list had been circularized for their opinions. On the question whether they were in favour of raising the fee for all cases in which the income was up to £420, 421 had replied in favour, 41 against, and a few gave no answer. On a second question, whether the fee should be, as recommended by the Committee, 15s. 6d. per case instead of 10s. 6d., 375 had replied in favour, 39 against, and 20 had given no answer. On a third question, whether they would decline to see patients in this class when a lower fee than 15s. 6d. was offered, 381 said that they would do so, 16 gave no definite opinion, and 66 no answer at all.

Dr. F. A. ROPER (Exeter) said that this dealt with an entirely new factor in medical practice. The motion was brought forward by one group of consultants—namely, the Ophthalmic Group. It appeared to him that the inclusion of this new economic class of patients within national health insurance introduced the need for a complete consideration of the new position by others than those in that specialist group. Sufficient time had not been allowed for consideration of these new proposals by consultants in general. The proper course was to refer this resolution to the Council.

Dr. A. S. GOLGH (Watford) said that if they were in future to have a united profession it must be driven home that the specialists would have to make the same sacrifice as general practitioners.

Mr. N. E. WATERFIELD supported the suggestion that this be referred back for further consideration. There had been no opportunity to consider the motion at leisure, and it had much larger bearings than as affecting the Ophthalmic Group.

Mr. BISHOP HARMAN said that the Committee had done its best to see if it could not refrain from making any alteration for non-insured patients, but it was almost impossible to make that distinction. He thought that the request made by their ophthalmic colleagues should be granted.

Mr. McCURRICH said that he still felt, in spite of Mr. Harman's argument, that this was not the time to accept this inclusion. In the case of insured persons they had, of course, no option.

The motion was carried.

The Association's "Journal"

Dr. E. H. RICHARDS (North Staffordshire) moved a resolution urging that the *Journal* should contain more articles for practitioners, giving reports of recent improvements in diagnosis and treatment, as opposed to reports on research. He acknowledged that there had been, particularly during the last twelve months, a great improvement in the direction indicated, but the opinion of many members in his area was that the *Journal* was rather more academic than practical. He himself was not a general practitioner, and the specialist had his own journals: They did not buy their *Journal* every week in order to study research. Some of them found themselves reading the *Supplement* only.

Col. R. G. GORDON (chairman of the Journal Board) said that this motion was obviously framed as a criticism, but it had been proposed in so kindly a way that he did not know how to answer it. The policy of the *Journal* had been to try to satisfy as far as possible all branches of the profession. It must be remembered that membership of the Association was not confined to general practitioners, but included specialists, consultants, and medical officers of health, and it was the object of the Editor to try to balance the various interests concerned. He might be forgiven for mentioning what had happened to the *Journal* during the war. It had been necessary to cut their coat according to their cloth, and to modify the *Journal* in various ways. Paper had been the great difficulty. It cost £17 17s. 6d. a ton before the war and now it cost £46 1s. 8d. Moreover, the supply allowed was far short of the previous allotment. For this and other reasons, including the absence of contributing staff, certain features had had to be dropped. One of these was the Key to Current Literature. The *Supplement* had to be bound in instead of being loose, because if loose it had to consist of a certain number of pages—four, eight, or twelve. The Editorial Department had had a very difficult time. He also wanted to congratulate the Advertisement Department on a most successful result in spite of increased costs in every respect. The mover had said that members did not buy the *Journal* to study research. But in fact they did not buy the *Journal* at all. It was included in their subscription, and the cost of the *Journal* last year was only 2s. 1d. per member. He hoped those who had put forward this motion would realize the editorial difficulties. If one took the current issue there was only one article in it—a subsidiary leader—which was not of great interest to the general practitioner. He believed they were serving the general practitioner well, but the general practitioner must bear in mind the other classes of members who had to be served.

The motion was lost.

Dr. RICHARDS further moved: "That as the *Supplement* is the only means of informing practitioners of current events there should be more complete reports of central meetings." This time, he said, he really had a serious criticism. Those who took an active part in the work of the Divisions were often asked what the Association was doing. If in reply they confined themselves to the *Supplement* they would not have a very ready answer. There should be more complete reports of central meetings. How would the present Conference, for instance, be reported? Representatives were given a very great responsibility. Dr. Campbell and himself from North Staffs represented 200 members. Those members should be able to read in print exactly what they, their representatives, had said, and what happened to the motions they brought forward, also as to what opposition was encountered, and what type of opposition. The *Supplement* provided an ideal vehicle. It was reports of central meetings, not so much of divisional meetings, that were needed.

Col. GORDON, in reply, said that Dr. Richards feared that the present Conference would not be adequately reported. There had been no Representative Meeting since the war, but he wondered whether Dr. Richards had looked at the reports of the Representative Meetings before the war and was prepared to say that they were not adequate. It had not been recent policy to report meetings of committees, other than the Insurance Acts Committee, and, of course, the Council, because committees represented a stage at which matters were thrashed out, and it was often inexpedient to report them. Council meetings since the war had been few and brief, and there had not been the usual number of central meetings to report.

The motion was lost.

Dr. H. S. PASMORE (Kensington) moved that members of the Association should be entitled to reduced charges for advertisements in the *Journal*.

Col. GORDON said that most of the individual advertisements were for assistants, partners, and so forth. Was it really good policy to differentiate between members and non-members in the case of these small advertisements?

Dr. A. W. WESTON (Dudley) suggested that the advertisement charges in the *Journal* were generally too high. With a guaranteed circulation of 43,000 a week the charges could well be brought down.

It was agreed to refer this motion to Council.

Medical Organization

Dr. T. M. J. STEWART (East Yorks) moved: That a department should be set up at headquarters to keep under constant review the factors determining, and relevant to, the remuneration of medical practitioners. The information collected should be available to the Insurance Acts Committee and to any other committee of the Association as desired, and the department should be under the control of a committee of general practitioners elected by the Divisions. His Branch felt that the Insurance Acts Committee did not have sufficient data to prove any case that they had to present, and therefore they did not impress the officials to whom it had to be presented. If necessary the department he was envisaging could employ experts to advise in the matter of compilation and presentation. It was a serious matter for the practitioners of the country if a case was not presented in the best possible way.

The motion was lost without debate.

Dr. H. S. PASMORE (Kensington) moved to refer it to the Council to consider in the interests of the profession the formation of a standing committee of general practitioners. At present two separate standing committees dealt with general practice—the General Practice Committee and the Insurance Acts Committee. This motion from his Division arose out of dissatisfaction with the trend of certain matters in general practice to-day. The dissatisfaction was based, among other things, upon the recent expansion of the insurance income limit without consultation with the practitioners who would do the work. Apparently the Government could alter its panel contracts at will, while the practitioner had to maintain his part of the contract to the letter. This and various other grounds for dissatisfaction gave rise to the feeling that there must be something wrong with the organization in the Association. They all recognized the enormous amount of work that the committees were called upon to do, but these innumerable activities prevented full consideration being given to major issues. If such a committee were set up to give unbiased attention to the findings of the General Practice Committee and the Insurance Acts Committee, it would be able to prevent a series of small retreats which, if they did not prejudice the position of the profession at present, might well do so in the future.

Dr. E. A. GREGG, as chairman of the Insurance Acts Committee, said that probably the proposer did not realize the particular character of that body. The committee and its annual Panel Conference was a piece of machinery through which insurance practitioners might make their opinions felt. It was so constructed that while in one sense, through the link there was between it and the Council of the Association, it was a committee of the Association, in another and very real sense it was something very much more, and he had never yet known the Council fail to accept at the hands of the committee what it knew to be the expressed view of the insurance practitioners of the country. To take any other step such as was proposed in this motion would be retrograde and would immediately provide their critics and opponents with a great deal of material. While the profession was indebted to the Association for the machinery, the Association made no attempt to fetter or control the opinion expressed through the committee.

The motion was lost.

The Conference adjourned until the following day. A report of the proceedings will appear in next week's *Supplement*.

PROCEEDINGS OF COUNCIL

A meeting of the Council of the Association preceded the Conference of Representatives on Thursday, September 11. Mr. H. S. SOUTTAR was in the chair.

Dr. A. M. Watts was co-opted a member of Council in place of Captain A. W. Gardner, representative of the Kent and Sussex Branch, who had resigned because he was on national service.

The Council instructed that its congratulations should be forwarded to the members who had received recent honours.

A report was made of the deaths of Dr. W. F. Brook and Dr. G. E. Twynam, former members of Council, and the Chairman was authorized to forward letters of condolence.

Congratulations were tendered to the Secretary, Dr. G. C. Anderson, on receiving the Fellowship of the Royal College of Physicians. Sir Kaye Le Fleming referred to the tact and wisdom which Dr. Anderson had shown in dealing with the Royal Colleges in the matter of the Medical Planning Commission, and said that this bestowal was all the more appropriate on that account. Sir Ewen Maclean added his congratulations.

The Central Medical War Committee was nominated. The Chairman stated that the Medical Superintendents Society had applied for representation, and he thought this was a reasonable inclusion. The Council agreed. The Protection of Practices Committee was also re-elected.

Dr. F. Gray was nominated as the Association's representative on the governing body of the British Postgraduate Medical School.

Award of Gold Medal

The Chairman of Council proposed: "That the Gold Medal of the Association be awarded to Sir Kaye Le Fleming in recognition of his distinguished work for the Association and the profession." He said that it was quite unnecessary for him to stress the claims of Sir Kaye Le Fleming to this honour. He had had a very distinguished career in connexion with the Association, and the very solid position which the Association had now attained with the profession and the public was due in no small degree to his efforts.

The motion was carried unanimously and with acclamation.

Supply of Milk to Domestic Consumers

A report was made to the Council on the subject of the medical certificate prescribed under the Sale of Milk (Restriction) Order. The Secretary stated that an indication had been given that all the practitioner would have to do would be to indicate the particular class of illness mentioned in the Schedule, but now in the medical certificate which had been forwarded from the Ministry of Food it appeared to be required that the practitioner in some instances should state the actual disease from which the person was suffering. That was quite a new point and a most material alteration.

Prof. Picken said that it was true that the certificate was no longer to be handed to the dairyman but to be sent to the Food Control Office. At the same time he thought it was unfortunate that it should have to go through that channel bearing the name of the disease from which the person was suffering, as it might fall into the hands of persons in that office who knew the applicant. Dame Louise Mellroy thought it was a breach of medical confidence and secrecy to insert the name of the disease or illness. Dr. Dain said that this new arrangement did in a way cut across professional secrecy.

It was agreed to protest to the Ministry of Food against that form of certificate which required the practitioner to insert the name of the disease or illness from which the applicant was suffering, and the forwarding of such certificate to the Food Control Office.

Business of the Executive Committee

Mr. Souttar reported that the Executive Committee had, on the instructions of the Council, given further consideration to its decision not to admit to membership of the Association alien practitioners who had been admitted to restricted registration. The committee adhered to its previous decision, but had given instructions that any alien practitioners admitted to temporary registration should be able to obtain the *Journal* at the reduced

subscription rate of 1½ guineas. The admission of these practitioners to membership of the Association involved considerable difficulties. The Council confirmed the decision of the committee.

Mr. Souttar also stated that a communication from the British Hospitals Association had been considered suggesting that that body and the British Medical Association should each nominate three representatives to form a standing liaison committee to consider matters of mutual interest. The Executive Committee had approved this suggestion, and the following had been appointed as the Association's representatives: Dr. Peter Macdonald (chairman of the Hospitals Committee), Mr. R. G. Newell, and Dr. Russell Brain.

Colonel R. G. Gordon (chairman of the Journal Board) described the arrangements which had been made for the printing and publication of the *Journal* following the destruction by enemy action in May last of the premises at which the *Journal* was printed. The Chairman of Council said that a most admirable arrangement had been made, the printing of the *Journal* was in every respect excellent, and the Association was indebted to Colonel Gordon and the Journal Board for the effort they had made to maintain this production at a high standard.

Dr. E. A. Gregg brought forward the report of the Protection of Practices Committee. He said that an important point which the committee was bearing in mind was that the acting practitioner should accept on behalf of the absent practitioner those persons who would ordinarily have gone on to the list of the latter had he been in his practice, and should attend them in the absence of that practitioner.

Dr. Gregg also submitted a report of the Insurance Acts Committee. Speaking with regard to the recent negotiations over the capitation fee he said that a firm promise had been given by the Minister of Health that at the end of the war the whole question of the capitation fee should be opened up in the widest possible way, and should the result be a higher capitation fee, necessitating further financial allocations, a Bill would be introduced into Parliament to give effect to it.

This concluded the meeting of the Council, which had lasted one hour.

MEDICINE TO-MORROW

In his presidential address to the Paddington Medical Society on the place of the doctor in the community of to-morrow, Dr. G. de Swiet said that modern wars altered modern life on so vast a scale that no amount of detailed planning made during the strife could be of much use. Nothing but big outlines could be of any help. There was a danger that unless we altered the character and the scope of our activities we might lose our claim to be a leading profession. We should not isolate ourselves by professional limitation of interests.

The conception of prevention of diseases was relatively new, and a further study of immunology might prove that the subject was by no means exhausted. Medicine would tend to be linked more and more with sociology, the first link having been established through public health, then hygiene, and later epidemiology. There were, he continued, periodic epidemics of a social kind, and the community of to-morrow might ask doctors to discover a remedy against these. Those who had predicted the advent of the present war might be able to suggest remedies. Wars, he said, were the outcome of cumulative grievances, real or imaginary, at home or abroad. It was the quick settlement of grievances, both national and individual, that would go a long way towards the prevention of war.

Another problem that might be tackled on preventive lines was that of marital conflict, a problem hitherto avoided by the medical profession and abandoned to the legal. Doctors were sometimes consulted on physical problems, but little on temperamental problems. Future generations would, he believed, blame the medical profession for not doing anything about a more judicious selection of chromosomes. Finally Dr. de Swiet referred to the community of to-morrow, stating that the information accumulated by teachers on the behaviour and character of their pupils was lost as soon as the latter left school and entered the outside world. Such information should be available to the doctor without his having to ask for it, so that constructive use could be made of it.

Correspondence

State Medical Service

SIR,—From the letter of Dr. E. U. MacWilliam (*Supplement*, August 23, p. 31) it is clear that at least some members of our profession realize that if the nation is wisely guided there will be after the war radical, in fact one might say revolutionary, changes in our whole system of political economy. Of necessity these revolutionary changes will involve both the medical services to the nation and our whole financial system. To argue about a State Medical Service as against our present system without considering the larger question in all its bearings seems to me like fighting about the paraplegia of a pernicious anaemia case while forgetting or disregarding the really important question of the whole blood-producing mechanism. If the present narrow escape of the democracies from total destruction by the totalitarian States does not convince our economists of the necessity for revolutionary changes if we wish to survive at all, nothing can save us from that total destruction in the near future.

I hope someone at head office is giving careful study to the whole question in all its bearings so that the profession may be given a considered and authoritative lead when the inevitable revolutionary changes are brought into being. Would it be possible to have a few articles of an educative nature in the *Journal* from recognized authorities on political economy, with special reference to the bearings of possible post-war changes on the medical profession and its duties to the nation? As a rule medical men have not the time to give to exhaustive studies of this sort, and therefore their opinions on such things as State Medical Service are not always as sound as they should be. It may be quite all right to insist on free choice of doctor, but it should be remembered that that in itself is valueless if we have

not a community in which to exercise that choice. Have our leaders and advisers fully explored all suggested ways of salvation, including Douglas Social Credit and Sir Richard Acland's "common ownership," in their efforts to find a way of escape from our present highly dangerous difficulties?—I am, etc.,
Ballymena, Sept. 1.
J. ARMSTRONG.

SIR,—As medicine marches on, the need for closer co-operation between general practitioners, specialists, and hospitals becomes more and more evident, and many now, it seems, are advocating the organization of these various services into a single State Medical Service. If such a service is to be established, then may we well ask—What of the future of the G.P.? Will he, as some would have us believe, be robbed of his independence, be doomed to become a mere sorting machine for hospitals and consultants, an issuer of certificates, a humble salaried unit of a Government Department? Worse still, enmeshed in a web of red tape, shall we see his hitherto suave bedside manner lapse into official abruptness, the cryptic symbols of his prescription disclosed in bold Roman type—in short, his mystic mantle snatched from his shoulders and the whole tricks of his trade exposed to the cold scrutiny of public opinion? And moreover, bereft of their friendly adviser, shall we see his patients obliged to carry their ailments to an impartial board of "specialists" and sink to the level of mere "clinical material"? I think not. And for this reason. However much the public and politicians may desire it, never can we make of medicine an exact science, and never can medical men and women be bound by rigid rules and regulations. The very nature of his (or her) work renders the doctor's comings and going erratic. Strictly limited hours of labour, regular holidays with pay, liberty to strike—all the cut-and-dried routine so important in the eyes of the industrial worker—are not for us. We cannot down tools in the operation theatre, abandon the woman in labour at the first note of the hooter, or insist upon our "rights" in the face of a matter of life and death. Willy nilly we must "carry on," and at all costs uphold the high ideals of our profession. But whether the proposed scheme be merely an extension of the national health insurance system or an "all in" State Medical Service, there is one thing the G.P. must never submit to have wrested from him—that is his individuality, for in my opinion it is just the innate sympathy, the personal touch between doctor and patient, which makes of the healing art a vocation and not a trade, and no sound medical system can afford to ignore this fact.—I am, etc.,
Sunninghill, Sept. 7.

ARTHUR E. FRANCIS.

SIR,—Dr. Lindsey W. Batten (*Supplement*, August 30, p. 36), having expressed his fear that those contemplating a State Medical Service must be thinking in terms of a dream State, then proceeds to draw his own picture in terms of an undoubted nightmare State. He declares none of the services he worked for seemed to want his best work, and generally draws a horrific picture, presumably founded on his own experience. Like Dr. Batten, I have both experienced private practice and worked for services, with little to complain of; but it is particularly on behalf of the L.C.C. school medical service, which he mentions, that I want to take up the cudgels. I have often cited this as a shining light of what a large service can be. When I first worked for them I was struck by three facts. There was a pleasant atmosphere of trust in their doctors; if something (e.g., free milk) was needed for a child the spirit was "do what is for the good of the child first, and justify it afterwards"; and, though the numerous forms opened up vast possibilities for red tape, barely the lightest of pink tape was in evidence. The credit for this was undoubtedly due to those running the service, who were medical men. If such a large service could be both efficient and pleasant to work for I see no reason why other ones should not similarly be so, provided an important tradition—of patient first, forms afterwards—is established and maintained. One way of achieving this would be decentralization into small units. At present our teaching hospitals receive State grants, but nevertheless run themselves. Part of the trouble at present lies in Government Departments having to be preoccupied with the taxpayer's money. But may one not hope that in the future a change of outlook and a realization of the value of health services may make the public

realize that "putting the patient first attitude" is more important than putting the necessity for rigid economy first. Or will the cynic object that such a charitable view of Governmental extravagance can only be expected where really large sums, as in a "costs + 10%," are involved?

The other point Dr. Batten makes is that the private patient rewards us nearer to our deserts than does the State. But unless we consider our deserts very meagre, what of the large section of the community who cannot pay an adequate sum, and to whom illness entails all the extra worry of financial strain? Some service must be provided for them. In actual fact it should not be impossible to devise a service whereby a doctor is left free to devote part of his time to those patients who wish to and can pay him.

Finally, what strikes me in the enormous controversy regarding the most efficient form of medical service is that, important though this question is, there seems to be a tendency to overlook a more important aspect, and that is that a doctor should be in a position to prescribe those things required for health: decent accommodation, fresh air, and adequate nourishment. Without these no service, however well planned, can properly achieve what is needed.—I am, etc.,
Tunbridge Wells, Sept. 1.

W. LINDSAY NEUSTATTER.

State Medicine—What is Not Wanted

SIR,—It is true some sort of State Medicine is inevitable; but having read the views expounded by your numerous correspondents on this urgent subject, one can only be struck by the diversity of opinions as to what form State Medicine should take. So much is this the case that perhaps more coherence could be elicited by starting from the other end—what is not wanted. One can nearly always obtain a fair agreement in discussing a destructive policy, and, anyway, it is a pleasanter occupation and requires less mental effort than formulating a constructive scheme.

As a start, and speaking from the general practitioner's point of view (for some variant of the G.P. is bound to survive to act the humble part of go-between or filter between the patient and his ultimate "disposal"—a horrible word in this connexion which is certainly not wanted), the G.P. must on no account become a clerk, enshrined in an office, complete with desk, typewriter, and an elaborate filing system. That kind of filter, in peacetime, should be anathema to all sane men, though perhaps not so much so to women. Unlike most filters, the efficiency of the G.P. should be judged more on the amount he lets through than on the residue, for the filtrate he deals with himself, only passing on the dregs to the specialist, hospital, or whatnot.

There are a few exceptional beings among us who can combine the duties of clerk and doctor in a most praiseworthy way, and a room could be found for these in any scheme, but most of us are not so constituted—the better the clerk, the worse the doctor. Forms 1066, 69, and 1212 rendered in triplicate must be dispensed with, and form-filling generally reduced to a minimum and never in triplicate. What necessary correspondence a medical service entails should be of an informal nature, and even certificates might be humanized.

Of course, all this sounds impossibly Utopian, for whoever heard of any public service that was not deluged with ink or throttled with paper? But it will have to be or medicine will suffer.

As for the patients, the poor patients—the less they are passed on from one department to another and generally badgered, the better. One has heard a lot lately of raising a race of super-men—may the Lord forbid!—and of "health-consciousness" and the old Chinese myth that the doctor was only paid as long as the patient remained well. Surely all this is wrong. Health-consciousness might well be the forerunner of neuroses. If a man is well, well! he's well, and from his point of view that is all there should be to it.

Preventive medicine can go much too far. Who wants to be for ever touching wood or continually inoculated against everything of himself, such as tonsils and foreskins, as libations to the gods of good luck! Preventive medicine can become as much a curse as the taking out of insurance policies. One can be over-armed and safety becomes a burden. I do not believe that prevention is necessarily better than cure. It's a stop-gap to be undertaken gently and kept well in

the twilight. And finally, after this war we want to be individuals, for, with the awful examples before one, it is individuality if anything one is fighting for, though what this latter has to do with a State Medical Service I'm not at all sure.

E. GRANGER, M.B.

Medical Planning and a State Medical Service

SIR.—I have read with interest, and I confess some qualms of conscience, the thoroughly honest forthright letter of Squadron Leader W. H. Gossip (*Supplement*, August 30, p. 35). Surely his is a just plea: do not decide the fate and mode of living of the younger members of the profession without consulting them. Now is certainly not the time to plan a State Medical Service.

The raising of the panel limit was simply announced: we were not consulted. It is debatable whether the profession or public desires it at all, but apparently the politicians were determined to "slip it over." Above all, let us be careful lest we are but the pawns being placed in position, prior to our movement, step by step, by shrewd party politicians preparing for a post-war period, already with an eye on snatching beforehand the probable propaganda of their opponents, without thought or care to the little pawns, except for the relish of a political game thoroughly well played. We may suddenly find that having sleepily acquiesced in the raising of the panel limit we have to all intents and purposes already agreed to a State Medical Service, without our knowledge.

While the profession as a whole is occupied, in one way or another, serving the war effort, it is in no fit condition to make drastic changes affecting our future, and it is grossly unfair to attempt such changes without both the profession and the public being in a position fully to realize their full implication.

Remember we are the trustees of Squadron-Leader Gossip and thousands like him, who hope to return to the practices and districts they love, and not to a State Medical Service, wherein we shall have lost the most precious of all our possessions—the right to practise our art in that part of the country or town of our liking, and among people with whom we live in harmony and according to our individual ideals.

I am for the present one of the trustees, and through Squadron-Leader Gossip's letter I have just become aware of my responsibility—and that of all of us at home.—I am, etc.,

Hull, Sept. 2.

R. D. B. WRIGHT, M.B., Ch.B.

Domiciliary Vaccination

SIR.—As a public vaccinator for thirty-eight years to a county borough and also a county area adjoining, I am fully convinced that any departure from vaccination in the homes of the people would be disastrous to the cause of vaccination. People would not attend clinics for this purpose. As one who has conducted child welfare clinics in three different county areas over a long period, I say quite definitely that there was never anything to suggest that they would. If some are indifferent about it at home they would never think of undertaking a journey to a clinic, and only such as are now known as "request" cases would be done. By visiting the homes doctors have a rare chance of explaining vaccination, which, if adequately done by doctors who will take the trouble, will greatly improve the number of consents and considerably lessen the number of blank journeys. I have also found great help from leaving copies of *The Truth about Vaccination*, a most useful (1d.) pamphlet issued by the Association of Public Vaccinators of England and Wales.

As an example of the benefit of visiting the homes, may I say that from my last list of eight names received from the vaccination officer on Form H, I vaccinated seven. (One had recently left the district.) Of the seven only two were "request" cases, and if I had not visited the homes of the others and given a brief explanation of the reasons for vaccination it is practically certain that not one of the remaining five would have been done—it is absolutely certain, too, that not one of these mothers would ever have thought of making a journey to a centre for this purpose.

As most public vaccinators are also private practitioners and run in vaccination along with their ordinary round, the extra-petrol argument seems of minor importance. As regards fees, it would seem that the solution would be to ask the local administrative authority—either county borough or county council—to increase the minimum fee of 1s. per case entered on the lists received from vaccination officers to such a sum as would com-

pensate for what are now blank journeys. It is in the power of such authorities to do this. It is not likely that the Ministry of Health would agree to holding vaccination clinics on the lines of child welfare and diphtheria immunization clinics when so much per session is paid, as this would be a fundamental alteration requiring "statutory" adjustment. We must assume, therefore, that even if it were made permissible to establish vaccination centres *vice* domiciliary visits, doctors would only be paid a fee for each person successfully vaccinated. Such a fee would undoubtedly be very much lower than the present fee for domiciliary vaccination, and a doctor would have to attend the centre, probably often at inconvenient but regularly recurring times, and, after waiting, might get no patient at all, and would not get even the above-mentioned shilling, as no list of children requiring vaccination would be received from the vaccination officer. His last plight would be very much worse than his present one.—I am, etc.,

Walter Warrington, Aug. 25.

JAMES BENNETT.

The Threepence Halfpenny

SIR.—I am somewhat exercised in my mind concerning the question of the remuneration offered to, and accepted by, the Special Panel Conference of July 31 in respect of the new entrants to insurance (incomes below £420 per annum). The effect appears to be as follows. A doctor practising in a densely inhabited area who has a full panel of 3,000 will, without accepting a single new entrant, be paid an additional 3½d. for everyone on his list. In other words, he will be made a present of about £45 per annum. On the other hand, a doctor practising in a more open neighbourhood, with a panel list of 1,000, and who accepts 250 new entrants, previously attended privately, will be paid an additional £22 on his increased list. Therefore the doctor who has no responsibility whatever for treatment of new entrants would be paid twice as much out of the increase in the fee of 3½d. per head as the doctor who undertakes the treatment of 250 of the new class. It sounds queer.—I am, etc.,

London, N.W.1, Sept. 7

W. A. M. SWAN.

Medical Records as Waste Paper

SIR.—At a recent meeting of the Isle of Wight Local Medical and Panel Committee a member recounted the following experience. An insured patient of his had been absent on active service. He returned to civil life and reported to his doctor, bringing a history of schizophrenia from the Service he had left. The doctor telephoned to the local Insurance Committee for this man's previous medical records. He received the following reply:

"With reference to our telephone conversation this morning, I find that all medical records more than three years old have been disposed of for waste paper. This was in accordance with the instructions of the Ministry of Health. I regret, therefore, the medical record of Mr. X cannot be forwarded."

My committee has instructed me to submit this letter to you for publication.—I am, etc.,

G. M. BALFOUR,

Hon. Secretary, Isle of Wight Local Medical and Panel Committee.

Cowes, Sept. 4

Speaking on the diagnosis and treatment of gas casualties at a meeting at Swansea which had been arranged by the Swansea Division of the B.M.A., in co-operation with the Ministry of Health, Prof. J. A. Nixon of Bristol emphasized once again the need for rapid first-aid treatment and cleansing; serious internal damage might be caused, he said, before an external blister was obvious. Ordinary thick male clothing, especially a rubber coat and an umbrella, would have a high protective value in the event of sprayed gas, but he viewed with less certainty the present vogue among women for stockingless legs and openwork shoes. Some of the worst cases of injury from gas in Abyssinia were due to unpreparedness and to lack of clothing. The cardinal principle in the treatment of gas casualties, after contaminated clothing had been discarded, was prompt and vigorous washing, especially of the eyes. So long as the public were prepared—and they should be with their respirators—and those responsible for the treatment of gas casualties were well versed in procedure, we could, said Prof. Nixon, face any gas attack which might come. The lecture was attended by about eighty doctors from the Swansea Division and the neighbouring area of the South-West Wales Division.

B.M.A. : Branch and Division Meetings to be Held

WILTSHIRE BRANCH: SWINDON DIVISION.—At Victoria Hospital, Swindon, Wednesday, September 24, 8.30 p.m. Dr. H. Crichton-Miller: War Neuroses.

B.M.A. : Meetings of Branches and Divisions

BERKS, BUCKS, AND OXFORD BRANCH: OXFORD DIVISION

At a general meeting of the Oxford Division, held at the Radcliffe Infirmary on May 21, Group Captain STRUAN MARSHALL gave a lecture on "Some Physiological Aspects of Flying."

Another general meeting of the Division was held at Radcliffe Infirmary on June 25, when the following clinical cases were shown: by Mr. J. PENNYBACKER, chronic sciatica due to adenocarcinoma of the lumbar region; by Dr. PICKLES, myasthenia gravis; by Lieut.-Colonel R. P. S. KELMAC, R.A.M.C., (a) march fracture, (b) fractured scaphoid of soldiers, and (c) feet showing types of corns and callosities; by Dr. NORAH ARCHER, glandular fever. Dr. FRED A. PRATT demonstrated the Oxford ether vaporizer No. 1 and apparatus for intravenous administration of fluids.

**Medical Forces of H.M. Services
Appointments****ROYAL NAVY****ROYAL NAVAL VOLUNTEER RESERVE**

C. J. Thomas to be Temporary Surgeon Captain.

Acting Surgeon Lieut.-Commander F. J. S. Gowar to be Surgeon Lieutenant-Commander.

Probationary Temporary Surgeon Lieuts. J. W. Warrick, E. O. Davies, J. A. N. Lock, and J. R. Gray to be Temporary Surgeon Lieutenants.

ARMY

Captain D. B. O'Sullivan-Beare, half-pay list, late R.A.M.C., has retired on account of ill-health, receiving a gratuity.

ROYAL ARMY MEDICAL CORPS

Major S. J. A. Walshe, D.S.O., retired pay, late R.A.M.C., has been restored to the rank of Lieutenant-Colonel on ceasing to be employed.

Captains (Temporary Majors) J. C. Barnetson, H. J. R. Thorne, and T. J. Moloney to be Majors.

Captain (Acting Major) B. Blewitt to be Major.

REGULAR ARMY RESERVE OF OFFICERS

Colonel R. A. Bryden, D.S.O., late R.A.M.C., has ceased to belong to the Reserve of Officers on account of ill-health.

TERRITORIAL ARMY**ROYAL ARMY MEDICAL CORPS**

Lieut.-Colonel J. A. Hooker, from Royal Artillery, Territorial Army, to be Lieutenant-Colonel.

Captain J. F. Hinksman has relinquished his commission on account of ill-health.

**TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY
MEDICAL CORPS**

Lieut.-Colonels F. A. Roper, A. J. Williamson, D.S.O., and A. C. Court, M.C., having attained the age limit, have relinquished their commissions and retained their ranks.

Wilson.

ROYAL AIR FORCE

Wing Commanders V. R. Smith, C. P. Barber, and G. H. H. Maxwell to be Group Captains (Temporary).

Squadron Leaders G. A. M. Knight, F. W. P. Dixon, C. R. Palfreyman, and C. A. Rumball to be Wing Commanders (Temporary).

Squadron Leader (War Substantive) A. S. Burns to be Wing Commander (Temporary).

Flight Lieuts. R. S. Peill, H. E. Bellringer, R. L. Soper, R. S. B. McClean, L. M. Crooks, D. J. Sheehan, R. F. Wynroe, and J. B. Wallace to be Squadron Leaders (Temporary).

Miss Cecilia D. Middleton and Miss Mary Robertson to be employed by the Royal Air Force, with the relative rank of Flying Officer.

RESERVE OF AIR FORCE OFFICERS

Squadron Leaders (War Substantive or Temporary) R. F. T. Grace, J. C. Smyth, and E. G. Howell to be Wing Commanders (Temporary).

Flight Lieuts. P. A. Lee, D. F. Cameron, E. Corner, F. W. G. Smith, W. Hall, A. H. Osmond, J. McGovern, H. S. Barber, and H. F. Harvey to be Squadron Leaders (Temporary).

AUXILIARY AIR FORCE

Squadron Leaders (War Substantive or Temporary) J. H. Williams, I. A. G. L. Dick, J. P. Huins, and J. H. Attwood to be Wing Commanders (Temporary).

Flight Lieuts. R. G. Smith, J. Aitken, A. C. Hendry, and E. C. Gross to be Squadron Leaders (Temporary).

ROYAL AIR FORCE VOLUNTEER RESERVE

Squadron Leaders J. C. Ainsworth-Davis and J. G. Stewart to be Wing Commanders (Temporary).

Flight Lieutenant J. F. Bromley to be Squadron Leader (War Substantive).

Flight Lieuts. A. Ronald, W. S. McKenzie, J. S. Harper, M. Gordon, G. H. Bateman, J. G. L. Brown, H. A. Graham, and J. Howkins to be Squadron Leaders (Temporary).

Flying Officers P. J. Blandland, H. Halson, M. J. Greenberg, L. J. Jacobs, G. R. Green, G. C. Barron, and H. T. Macauley to be Flight Lieutenants (War Substantive).

COLONIAL MEDICAL SERVICE

The following appointments are announced: R. A. S. Cory, M.B., Ch.B., Senior Medical Officer, Jamaica; J. D. Reid, M.B., Ch.B., D.P.H., Assistant Bacteriologist, Sierra Leone.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following postgraduate courses: (1) Final F.R.C.S. comprehensive revision course, daily, 10 a.m. to 1 p.m., from September 29 to October 17. (2) Final F.R.C.S. practical operative surgery course on the cadaver, Mondays, Wednesdays, and Fridays, at 2 p.m., from October 6 to 31. Both these courses will be given at the Royal Cancer Hospital. (3) Revision course in anaesthetics, daily, September 29 to October 11, at the Radcliffe Infirmary, Oxford.

A series of lectures on "Treatment of Fractures, with Special Reference to War Conditions" will be given at the British Postgraduate Medical School from Monday to Friday, October 13 to 17 (both days inclusive), beginning at 10 a.m. daily. The fee for the course is £5 5s., but a limited number of officers of the armed Forces will be admitted free on receipt of a leave certificate. Applications for admission should be addressed to the Dean of the British Postgraduate Medical School, Ducane Road, W.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—St. Mary Islington Hospital, Highgate Hill, N.: Wed., 2 p.m., Final F.R.C.S. Clinical Course. APPOINTMENTS

MORGAN, A. W. J., M.R.C.S., L.R.C.P., D.P.H., Officiating Chief Medical Officer, Bengal-Nagpur Railway.

SIMMONS, R. W. A., B.M., B.Ch., Examining Factory Surgeon for the Eastleigh (formerly Bishopstoke) District (Hampshire).

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 27 1941

British Medical Association CONFERENCE OF REPRESENTATIVES OF HOME DIVISIONS SECOND DAY

The Conference reassembled on September 12, Dr. H. G. DAN again occupying the chair.

MEDICAL ORGANIZATION

Divisional Discussion Groups

Dr. H.-S. HUTCHISON (Halifax) moved to ask the Council to make a strong recommendation to all Divisions to organize within themselves discussion groups for the consideration of the future of medicine, the results of the deliberations to be forwarded to the central body for approval, assessment, and publication. He began with an expression of regret that on the previous day, in moving a resolution which had provoked a certain amount of controversy, he had not had the good sense to compliment the Council on forming a Medical Planning Commission. He had been so obsessed with the method of appointment as to forget the merit of the thing in itself. He went on to say that the individual practitioner, by virtue of his work, was far too much detached from medical politics, and the Conference had an opportunity to formulate a plan which might bring him more closely into the shaping of what lay ahead. One day the members of the profession might have to vote on some scheme presented to them, but in his opinion at present 95% of the profession were quite unable to register an effective vote. He asked the Conference to instruct every Division to take upon itself the business of educating its members. The best method was not by means of unwieldy Divisional meetings, but by discussion groups of six to ten members, in which even the most timid might have his say. Every doctor ought to decide for himself the details of future medical service—it was not the grand plan but the details which counted. It was the small signs and symptoms they looked for in their daily diagnosis, and it was the small signs and symptoms they had to look for in this matter of a medical service scheme. What he was afraid of was that the Commission would present them with a plan, probably a very good plan, but one which would evoke no such interest as would be forthcoming if the electorate had had the opportunity of studying the problem for itself. The results of the groups' deliberations should be collated and subedited by a central body and then presented for the opinion of experts, after which a Conference might be called with adequately instructed delegates. "The destiny of the profession may be decided very soon, and this Conference to-day may be the last effective opportunity you will ever have of a say in that destiny. The instruction of the individual medical practitioner is the keypoint in preparing a plan for the future."

Prof. R. M. F. PICKEN said that he was entirely in accord with the motion, except for one word which required qualification. The motion asked the meeting to instruct the Council to "publish" this material, but such publication might be impracticable at the present time. He proposed that before the word "publication" there should be inserted "as far as practicable."

Dr. HUTCHISON accepted this amendment.

Dr. R. W. MCCONNELL (Nottinghamshire) moved an amendment: "That the results of these deliberations should not be published, but, with the findings of the Medical Planning Com-

mission, should be referred to the Divisions and to the Representative Meeting."

Dr. E. A. GREGG said that it was of the utmost importance that the members of the profession should not be faced with a mass of material that had already been dealt with by other people and asked to give a hurried decision on it. In St. Pancras they had already started discussion groups and proposed to continue them. He agreed with a further suggestion in the motion that members of the profession who were not members of the Association should be invited to attend. As for publication, the results of deliberations of this kind would go out to the constituencies through many normal routes—through meetings of the Association as well as in the *Journal*—and he deprecated the requirement that the results should be forwarded to a central body for approval, assessment, and publication.

Mr. P. W. L. CAMPS said that South Middlesex warmly supported this proposal. If the work of practitioners was passing from them as a result of encroachments it was because they had not taken a keen enough interest as individuals. It was essential that the discussion groups should place the results of their discussions periodically before the whole Division.

Sir KAYE LE FLEMING said that he thought the whole Conference was agreed on this proposal, but it was difficult to find words in which to put it quite clearly. He suggested that the motion after the word "medicine" should read as follows: "And that it be left to the Council to work out the details of assessment and publication of the findings, so that all members of the profession, whether members of the Association or not, may have the opportunity of free and full discussion."

In this form the motion was agreed to without dissent.

Organizations of Branches and Divisions

Dr. A. B. CAMPBELL (North Staffs) brought forward a motion declaring the time to be opportune to consider reconstruction in the organization of the Association: (1) Divisions should be so arranged that it was possible for every practitioner to attend meetings; (2) Branches should be regrouped according to distances; (3) area councils should be formed; (4) grouped Divisions must meet a certain specified number of times a year; (5) membership of Council should be limited to a certain number of years; (6) additional permanent officials should be appointed to visit Divisions; and (7) the whole profession should be asked, to support a Division engaged in a fight.

He said that this series of resolutions was drawn up at a well-attended meeting in his Division. More intimate contact was wanted between members of the Council and their constituents. The area of Branches was unwieldy; the Branch of which North Staffordshire was a part extended southwards down to Buckinghamshire. The constitution of the Council, he believed, was drawn up in the 'nineties, with occasional amendments since, and what was right for the 'nineties did not serve the purpose fifty years later. He wanted also to ensure that younger men had a chance of gaining a seat on the Council. This might be done if, after a number of years of service, some members of Council were made honorary or alderman members, so that their

advice would be retained, although they would have no vote. As to the secretariat, it was fully appreciated that the permanent officials were at present fully occupied, but though it was not easy to train such officials, it did seem to be necessary to have men who could visit the Divisions when required and at least once a year.

Dr. F. A. ROPER (Exeter) said that even if it was agreed that the time was now opportune to consider the basic organization of the Association *ab initio*, there was really on analysis very little that fundamentally needed altering. It was already the duty of the Council to approve the areas of Divisions, and naturally Divisions had been mapped out with a view to general convenience. Again, in view of the trend of legislation it was found to be of constantly increasing importance that, to save absurd duplication, Division and Branch areas should be co-terminous with local government areas. As for the constitution of the Council, twenty-two of its members were at present elected by direct vote of members throughout the country, and twenty others were elected by members of the Representative Body, themselves presumably on the whole better able than most people to assess the merits of anyone proposed for the Council. There was no case for altering the constitution of the Council, and the whole motion was unnecessary and should be turned down.

Sir KAYE LE FLEMING said that anything more ludicrous than the statement that the Council was framed on ideas that had not been reviewed for the last forty years he could not conceive. The organization of the Association was continually being changed. The great virtue of it was that it was open to change from time to time, and most of the points raised in this motion were continually under review by the Council itself. "You have got a very good machine; if you would take a little less notice of the machine and pay a little more attention to the spirit you put into it, it would go better." The idea was put forward that after a certain term of years a member of the Council should automatically retire. But that, in fact, was provided for in the constitution, and in order to retain the services of old and valuable members of the Council, it was provided that they might be elected by the Representative Body as a whole after they had served their full term. He asked the Conference to turn down this motion.

Dr. D. O. TWINING (Plymouth) said that the proceedings of the Conference reminded him of an ancient pedagogue who illustrated the four stages of a man's life by saying that in childhood we knew a great deal and did not realize it, in adolescence we knew nothing and thought we knew everything, in manhood we spent our time learning laboriously the things we ought to have known years before, and in old age, when we knew a great deal, we found nobody to listen to us. On the previous day the Conference had shown itself in the adolescent stage; that morning it had reached manhood and was showing a great desire for more information. The difficulty which those of them who were country practitioners found was in getting people together to join in discussions. One method which had been found to work fairly well in a scattered rural area was the method of election to the Panel Committee by dividing up the area into a number of districts, each of them with a Panel Committee representative, who was elected by eight or twelve men and was more or less able to discuss matters with his constituents. But it was often very difficult to get men to go even short distances to discuss matters which were vital to their profession and interests.

Dr. F. W. CHEESE (East Kent) said that there was machinery at headquarters for dealing with changes of boundaries of Divisions, and in Kent several Divisions had been reorganized. If North Staffordshire had been unwieldy for some years it was its own fault.

Mr. H. J. MCCURRICH (Brighton) said that some Divisions had become over-large through no wish of their own. His own Division had from time to time taken in certain others which had become moribund.

Dr. T. R. DAVIES (South-West Wales) said that his Division extended for seventy miles from end to end. The Council should consider whether large Divisions could not be split up. The idea that the Branches must follow county boundaries had had to be modified in certain districts owing to the regionalization plan for hospitals.

Dr. J. B. MILLER said that the present arrangement of Divisions was very recent and was due entirely to the passage of the Local Government Act, 1929. It was essential that the practising doctors should have the closest possible relation with the medical officer of health, and that could only happen if the Division and Branch corresponded entirely to local government boundaries.

The North Staffordshire motion was lost.

Dr. S. W. SWINDELLS (Grimsby) asked the Conference to express the opinion that in matters of important policy the principle of a plebiscite should be adopted. He said that this was really an expression of dissatisfaction with recent action of the Council.

The CHAIRMAN said that the Association could at any time take a plebiscite on matters of policy which it felt should be referred to individual members of the Association. He was bound to say that many of the motions on the present agenda displayed ignorance on the part of Divisions with regard to their own machinery.

This motion also was lost.

CERTIFICATION

Industrial Certification under War Conditions

Dr. W. A. KIRKPATRICK (Cleveland) moved to ask the Council to review the question of industrial certification under war conditions. He said that, Cleveland being an industrial area, practitioners were inundated with requests for certificates. He hoped the Council would issue some definite instruction and not leave the matter in the air. As it was, some medical men refused to issue certificates, whereas others were ready to issue them. Another matter which was likely to arise related to the Essential Works Order. The National Service officer had power to demand from doctors detailed reports on patients as to whom there remained some doubt concerning their capacity for work. It would be useful to have some instructions whether they should charge for these certificates, and, if so, whether these should be charged to the person making the request or to the National Service officer.

The SECRETARY (Dr. Anderson), by permission of the Conference, made a statement on the subject. He said that several months ago he was in contact with the Ministry of Labour in connexion with one of the certificates which was being demanded of practitioners. This was the certificate required under the Transfer of Labour Order. He had a discussion with one of the chief officials of the Ministry and, realizing that the same situation might arise as arose during the general strike in 1926, he felt that a general plan should be adopted to obviate some of the difficulties which then presented themselves. The arrangement arrived at tentatively was that in each area there should be an officially appointed person to whom doubtful certificates could be referred, and it was obvious, in his judgment, that that person should be a medical man. This meant that the practitioner would give on request to his own patient a certificate in connexion with the Transfer of Labour Order, but that if there was doubt or if the certificate was not likely to be accepted for one reason or another, there should be appointed a medical man to whom the case could be referred. The man suggested was the examining surgeon, formerly known as the certifying factory surgeon, and the arrangement was that he should receive a fee of 5s. Later, however, he learned that the Treasury was not prepared to sanction that arrangement, and so the whole thing fell to the ground.

The second point was in connexion with the attendance bonus certificate. He realized shortly after the introduction of that scheme that trouble was likely to arise, and it was not long before resolutions were forthcoming from the Divisions in regard to that matter. He thereupon got in touch with the Mining Association, which was anxious also to get in touch with him in order to impress upon him the necessity for issuing an instruction—as they called it—to members with regard to the giving of these certificates. He suggested that the best plan would be first to have a discussion between the representatives of the Mining Association and of the mine workers, because he held the view that before any proposal could come into effect the medical profession should be consulted. The chairman and

secretary of the Mining Federation had been good enough to come to the office, and he listened to their argument that practitioners should be more free in giving these certificates. He had to tell them that so far from helping them he was going to oppose them and to recommend that certificates should not be given by the medical profession generally in connexion with one day's absence from work. He did so because in the vast majority of such cases there were bound to be insufficient clinical data on which the medical man could make up his mind to give a certificate. He now had a letter from the secretary of the Mining Association, dated September 5, and enclosing a copy of an agreed statement regarding a new arrangement which operated as from September 1. The effect of it was that while the conditions of qualification operated in respect of payments of the bonus for days prior to that date, a worker was not disqualified for payment in respect of work after September 1 by reason of absence on account of sickness on any other day. This, therefore, disposed of medical certificates in future so far as the attendance bonus was concerned.

Another point, however, was going to arise. The secretary of the Mining Association stated that the question of satisfactory evidence of incapacity through sickness might come forward subsequently in connexion with the Essential Work Order. The position until recently was that, both under the Essential Work (Provisions) Order, which did not apply to coal mines, and the Essential Work (Coal-mining Industries) Order, absence, even for sickness, constituted a disqualification for the guaranteed wage. Now, however, the first of these Orders had been amended to provide that a person shall not be disqualified if his absence is due to sickness and, if required, he submits satisfactory evidence to that effect, and the Mineworkers' Federation was likely to suggest a corresponding amendment in the second Order. It was in connexion with the multiplication of certificates that the Ministry of Health had been approached and their assistance requested. This approach was not a recent one. He himself had been personally in contact with the Ministry of Health, asking them to give consideration to this difficult problem, and quite recently there was a conference at the Ministry, attended by Dr. Hill, who suggested that there should be some better co-ordination between Government Departments which were either demanding or stimulating requests for certificates, and that before any new certification was foisted upon the profession consultation should take place between the Government Department concerned and the Ministry, in which consultation the Association should have a share.

There were a number of certificates that doctors must give, but there were a number of others required of the profession at the moment that need not, in his judgment, be given at all. One of these was the certificate in connexion with milk for children under 5. Surely that did not require a certificate from a medical man. There were also the occasions on which a practitioner was required to witness the signature of a person presenting a document; he should be relieved of that. If it was possible to bring about central consultation before the certificate requirements were made public a distinct gain would have been achieved. (Applause.)

Dr. C. W. SOMERVILLE (Lothians) read a letter which he had received from a subsidiary company of Imperial Chemical Industries: "We enclose one book of medical certificate forms for the purpose of informing us of the illness of any of our employees who are your patients. We propose to pay you 1s. per certificate." The form of the certificate was: name; address; date from which the man was unfit to work; the nature of the illness; and the date on which he was fit to resume work. Employers who paid wages when a man was absent were entitled to a certificate, but the question was whether 1s. was enough and whether the employers had any right to ask the nature of the illness. He intended only to say whether it was an accident, an illness, or an infectious illness. With regard to school certificates, some practitioners refused to give them, some gave them and did not charge, and others gave them and charged for them. The attendance officer visited every sick child, and therefore it seemed to him that certificates were not required. It was very desirable that these matters should be on a uniform basis.

Dr. A. W. WESTON (Dudley) said their first duty to a patient was to treat him; a second duty was to certify whether he was

fit or not fit for work, but why they should take upon themselves all sorts of extra burdens when they were overworked already he could not understand.

Dr. HOWIE WOOD (Isle of Wight) said that a point of principle of some importance was the use of N.H.I. certificates for other purposes. It was expressly laid down and printed on each N.H.I. certificate that it was to be used only for national health insurance purposes, but this rule was often contravened. Even a Government Department went so far as to insist upon this certificate being exhibited for evidence of incapacity. In his area the engineering department of the Post Office Telephone Service, whose staff were on national health insurance, but not on the capitation list of the Post Office doctor, insisted that the insurance certificate be submitted to them by the insured person, after which it was returned to him for submission to his society.

The Cleveland motion was carried.

Unnecessary Certificates

Dr. W. S. MACDONALD (Leeds) had a further motion on the paper asking the Council to give special consideration to the increasing demands by State Departments and employers for certificates, but in view of the satisfactory statement of the Secretary he did not move it. He hoped, however, that the Council would also take up the question in its relation to the general public. The general public was making far too many requests to doctors for unnecessary certificates on all manner of subjects.

Dr. MAXWELL ADAMS (Lanarkshire) moved:

That this meeting views with concern the apparent apathy with which representatives of the Association permit ever-increasing certification to mount unhindered, apparently without protest, to the detriment of general practitioners, who form the majority of the membership of the Association.

Multiple certification, he said, was interfering with the professional work of the practising doctor. On a busy day in his consulting room a doctor was signing certificates for from 20 to 40 people, "for patients yet unborn to patients who have crossed the bar." As a consequence of this the good relations between doctors and patients were being frayed.

Dr. J. W. BONE said that the question of medical certification had always been a difficult one, but under war conditions it became a burden of such magnitude that the general practitioner in many areas found that it interfered materially with his work. The Conference had already passed a resolution on the subject, with which he was sure everybody concerned in the central organization would be in full agreement. Under war conditions the committees which dealt with these matters had not been functioning, but a small General Practice Executive Committee had been working, and it was probably to this body, strengthened for the purpose, that the Council would remit this question. He suggested that the movers of this and other motions on the agenda should withdraw them and embody their views in letters to the Secretary, which would be available for the information of the committee concerned. Those at headquarters did not need any arguments on this subject: all they wanted was detailed information. Every Division in which there was a grievance on this matter should send in some kind of document stating exactly what the grievance was.

Dr. W. N. LEAK (Mid-Cheshire) pointed out that these certificates were of great importance to employers. He was a member of the Advisory Medical Council of Imperial Chemical Industries, and they found extraordinary variations all over the country in this question of one-day or two-day sickness absence. It was of the greatest importance to know whether such absence was due to sickness or to slacking, and unless these certificates were given, and given accurately, it would mean some interference with the man-power of this country. In one firm with over 1,000 employees the one-, two-, and three-day absences accounted for nearly 50% of the total absenteeism due to sickness. If practitioners said that these certificates were a nuisance and that they did not want to issue them, they were not pulling their weight in the national effort.

It was agreed unanimously to proceed to the next business, and it was understood that this and other motions dealing with certification would be referred to the Council.

REMUNERATION OF PRACTITIONERS**The Recommended Increase of Private Fees**

Dr. E. WARD (Torquay) had a resolution on the paper which read: "That this meeting regards the recent advice of the Council to raise fees by 20% as inopportune, and indicative of a serious ignorance of the conditions of general practice at the present time," but in moving it he desired to withdraw the words after "inopportune." He said that, with decreasing incomes and increasing taxation, it was certainly not advisable to impose any increase of private fees upon the public. There were no doubt districts in which higher fees might be charged, but this should not be put forward as a general policy applying to the whole country.

Dr. J. W. BONE said that in May last the Council decided, owing to the rise in practice expenses, to recommend to the profession that general practitioners should increase their private fees by 20%. No representations to the contrary effect had been received from any Division, and this was the first time he had heard any suggestion that they were unaware of the conditions of general practice. He believed that the recommendation had met with general acceptance. It was a recommendation, not a mandate, and any Division which decided not to take this advice was fully at liberty to do so.

Dr. S. W. SWINDELLS (Grimsby) gave some figures of earnings of persons in his constituency, from which he inferred that it was unreasonable to ask these people at any rate to pay 20% more in doctors' fees. As it was, many people in his locality could not afford to pay even the ordinary fees. This was specially the case when the bread-winner of the family was on active service.

The motion was lost by a large majority.

Fees derived from Insurance Companies

Dr. G. PRIESTMAN moved that the principle of the 20% increase should be applied to all fees, including those derived from public health authorities, insurance companies, and other corporate bodies. He said that whatever happened to the fees charged to private patients, the increase should certainly apply to contract figures, but in the case of fees paid by insurance companies particularly they were up against a brick wall. The usual fee of £1 1s. payable for medical examination had been unaltered since, he believed, 1914. If £1 1s. was a fair remuneration then, £2 2s. should be paid now. The comprehensive character of life insurance examinations was well known, and many of the companies required the filling up of a number of foolscap sheets of questions. In the opinion of his Division the whole question of payment for life insurance examinations should be considered by the Council, and negotiations should take place between the Association and the companies in order to obtain a more satisfactory remuneration.

Dr. J. W. BONE said that the final settlement of insurance companies' fees was made in 1919, but the Association had had many brushes with the companies since then. He was entirely in favour of trying to get adequate increases under war conditions for all this work, and the Council had recommended that the increase should apply to contract practice as well as to private fees. But it had deliberately excluded from its recommendation some of the bodies mentioned in the Bradford resolution, particularly insurance companies. Those companies to-day had their difficulties. They existed by receiving money and investing it, and they were now all up against the position that on the money which they invested at the present time they could get only a poor return. It would be difficult to persuade those controlling these companies that it was an opportune time for them to increase their medical fees. He suggested that this motion be modified into a reference to Council to consider the subject, and not, as at present, a recommendation to take action.

The CHAIRMAN said that the last time the insurance companies were tackled on this subject they gave the flat answer that if doctors insisted on putting up their fees they would do away with medical examinations altogether.

The representative of Bradford agreed that his motion be referred to the Council, and other like motions were also referred.

Dr. D. M. MACHERMAN (Outer Islands) asked the Conference to consider the remuneration of practitioners in the Highlands and Islands. Owing to the increase in professional expenses, cost of living, and transport costs, the medical service grants and mileage grants, as well as the insurance capitation fee, were inadequate. The work of doctors in this area who received poor law medical salaries had been considerably increased in recent years, but the salaries had not been raised.

Mr. HUGH MILLER (Inverness) spoke to the same effect. Practitioners in the Highlands and Islands Medical Service were given a special grant, but not the mileage grant under the Insurance Act, and he urged that they be placed on the same level as the rest of the insurance practitioners of this country.

The CHAIRMAN said that the Conference was glad to welcome these representatives from remote areas, and they could be sure that the Council would consider their case along with the other resolutions and do its best to make an improvement.

Economic Status of the Profession

Dr. G. DE SWIET (Kensington) moved:

That the Council be asked to fight more whole-heartedly for the livelihood of practitioners, their remuneration (aiming at a capitation fee of 15s. per annum for insured persons), their war damage compensation, their pensions (A.R.P. and others), and a more equitable distribution of jobs.

He said that the recent history of the insurance capitation fee would be in the minds of all representatives. There was a good deal of criticism at the half-heartedness with which the practitioners' case had been handled. He also desired to call attention to the unfairness with which practitioners were treated over war damage compensation as compared with large business firms who had had their premises destroyed. He thought there should be a war damage department for practitioners which would carry out its work altogether apart from any charitable activities. At the present time doctors had to pass a veritable means test before they could make an application for a Government advance, and even then, having gone through that humiliating and exacting experience, they were liable to be turned down. He had never heard of anyone getting more than £15 compensation. As to the more equitable distribution of jobs, there should be some broad lines to guide those responsible for making appointments, and Government appointments should not be a preserve for small circles.

Dr. E. A. GREGG said that there was more in this motion than met the eye. This was a blow aimed at the Association and its activities by those who were "willing to wound and yet afraid to strike." He repudiated the aspersion on the Association which appeared in the first part of this motion. Speaking for the Insurance Acts Committee, of which he was chairman, that body had used every endeavour on behalf of the insurance practitioner to get his capitation fee increased. There was only one card in the pack which would take every trick, and that was refusal of service. Was there any sane member of the Conference prepared to say that they could at the present moment go to the Ministry of Health and say they refused service? Dare they say it without consulting the profession? And short of saying it, what could the committee have said more than it had said already? It was asked by the Ministry to give its recommendation to certain proposals. It declined to recommend them, but it was bound to place them before the profession, as it did at the recent Panel Conference. The committee refused to attempt to coerce the Panel Conference to accept those terms. It took the decision of the Conference, which was called specially for that purpose. Those who blamed the Association and the committee seemed to have shut their eyes to the fact that the decision was the decision of the Conference. It was a decision made under protest; the Conference felt sore, as they all did, at the way in which the Ministry had dealt with them. But he wanted any critic to tell him how, at the present time, they could have done any more than make their protest. While they did not get what they wanted, they did get some things. They got a firm undertaking from the Minister, emphasized and underlined at two discussions with him, that the question of the capitation fee should be reopened immediately after the war, and in a way that had not been done before, right from A to Z. That was quite a good thing, and it was up to the pro-

session to make the very best of it. They had also got all that they asked for on the question of mileage, and on that of an additional sum for practice expenses. They had the explicit statement from the Minister that in what they had been offered there was no element in relation to cost of living, and when an award was made to meet the increased cost of living in the case of any class comparable with themselves, the case under that heading would come up for consideration. He resented this motion from Kensington and hoped the Conference would throw it out. (Applause.)

The CHAIRMAN OF COUNCIL (Mr. Souttar) said that the Council had done everything in its power to obtain the best terms it could in regard to compensation for air-raid injuries, but as a profession they had no greater claim than other people to be compensated for war damage. They stood to take their injuries just as did others in the Civil Defence Service, and they were prepared to place themselves whole-heartedly at the service of the country. They had done their best to obtain an improvement in conditions of work for the profession, but surely the country came first? (Applause.)

Dr. DE SWIET said that he had not asked for special treatment for doctors, but was not prepared to take worse treatment for doctors whose surgeries had been destroyed in air raids than was meted out to big business firms whose premises had suffered a similar destruction. It was not a question of patriotism. In that respect he did not require a lesson from anyone in that hall.

The Kensington motion was lost by a large majority.

Salaries in the E.M.S.

Dr. F. W. CHEESE (East Kent) brought forward two motions, one declaring that the salary scale for whole-time members of the Emergency Medical Service, especially those in the £550 per annum grade, was inadequate and unjust, and the other that the allowance of £100 for expenses paid to doctors retained in the service in the coastal areas was insufficient. He said that the majority of doctors holding these posts had families to support and were being compelled to break in on their savings. The salaries did not compare favourably with the scale laid down by the Association for senior medical officers employed by a public health authority.

Dr. BONE thought the Conference was not sufficiently informed to pass such a sweeping condemnation as the motion implied on the financial arrangements for carrying on this Emergency Medical Service.

The SECRETARY (Dr. Anderson) said that the fixing of these fees dated back to before the start of the war. At that time, when it was not known what would happen, they set themselves to agree with the Ministry on a scale corresponding approximately to the pay which a medical officer would receive if he went into the Army. The £550 scale, with the £100 in lieu of board and lodging, corresponded to the pay of a captain or lieutenant. The whole idea of the scales at that time was that one Service should not be more attractive than the other. When trouble arose in the coastal towns they were faced with the situation that the practices of the medical men there were disappearing because of the evacuation of the population. Representatives of the Association went to the Ministry to see what could be done to safeguard the interests of those men, and a scheme was arranged in towns like Dover, Folkestone, and Margate which gave a selected team of men the opportunity to live on in those coastal towns, providing the necessary A.R.P. and hospital services, as well as domiciliary attendance on the people who remained. A bargain was struck on the basis of £550 per annum, plus £100 in lieu of board and lodging. But in addition the men were allowed to participate in the Protection of Practices Scheme as well, and a conference was held at the Ministry of Health, when the actual division of the money was agreed to by the representatives from those towns themselves. At headquarters at any rate it was considered to be a good stroke of business for men whose livelihood was disappearing at a critical time. He suggested that they should not be led away by the simple statement that the £550 per annum was inadequate without knowing the conditions attaching to the whole situation.

Dr. C. G. TAYLOR (East Norfolk) asked the Conference, in fairness to men in the coast towns, to give their case some sympathetic consideration.

Dr. W. N. LEAK (Mid-Cheshire) considered that extra allowances should be given for wives and children.

Dr. CHEESE said that £550 a year plus £100 might sound all very well, but the expenses of running a practice had to be considered, and the case was not on a level with that of medical officers in the Army.

The resolution declaring that the salary scale was inadequate and unjust was lost by 22 votes in favour and 34 against, but the further motion that the allowance for expenses in coastal areas was insufficient was carried.

Fees of Medical Officers of First-aid Posts

Dr. W. A. KIRKPATRICK (Cleveland) moved to ask the Council forthwith to obtain a fresh contract for medical officers of first-aid posts and Class III Emergency Medical Service officers, such contract abolishing the overriding maximum clause. His Division felt that in the event of being called upon to act under the contract practitioners should be paid for the work they had to do. The overriding maximum clause limited the amount they could be paid, however much work fell to their share.

The DEPUTY SECRETARY (Dr. Hill) said that when the terms of service of E.M.S. officers were first negotiated just before the war the overriding maximum for consultants and specialists at 2½ guineas per session was 120 guineas a quarter, and the overriding maximum for general practitioners, who were paid at the rate of 1½ guineas per session up to five sessions and £1 6s. per session thereafter, was 75 guineas a quarter. Following representations to the Ministry, the overriding maxima were altered. They were doubled and applied to six-months periods instead of quarterly periods, the understanding being that practitioners on a sessional basis would continue to render service at such sessions as were required of them throughout the whole period even though in the early part of the period they had achieved the maximum remuneration permissible. In regard to first-aid posts, however, the maximum was a daily one. A little while ago the Ministry asked whether it would not be appropriate for the same six-months system to apply to first-aid posts as already applied to E.M.S. hospital sessions. The reply on behalf of the Association was that they agreed that the parallel was a sound one, but that if the Ministry proposed to apply the six-months maximum to first-aid posts they would no doubt at the same time, in order to bring it fully in line with the E.M.S., withdraw the daily maximum of three guineas. That led to a prolonged delay in the discussions, but the Ministry had asked representatives to meet him next week to discuss the matter further.

The CHAIRMAN said that as the matter was so actively under discussion it might be wiser not to pass any special instructions at that Conference. The mover of the Cleveland motion agreed, and the motion was withdrawn.

EXTENSION OF MEDICAL BENEFIT

The New Insurance Group

Dr. P. H. TAYLOR (Camberwell) moved:

That this meeting approves in principle the extension of national health insurance services to cover dependants of insured persons with incomes up to £400 per annum.

He said that the Association had strongly recommended that dependants of insured persons up to £250 per annum be included in the insurance scheme, and if there was a case for the inclusion of people earning up to £420 a year their dependants should come in.

Dr. GREGG hoped the Conference would not touch this proposal. It ought to have proper discussion in the same way as the question of the inclusion of the original dependants was discussed some years ago.

Dr. BONE moved to proceed to the next business, and this was carried.

Dr. KIRKPATRICK (Cleveland) had a motion:

That this meeting, having ascertained that the great majority of panel practitioners have no desire to include on their list as panel patients the class of non-manual workers earning between £250 and £420 a year . . . asks the Council to advise insurance practitioners to refuse to undertake this service.

He said that no adequate arguments had been brought forward for this extension, and he thought the Government had been guilty of a breach of contract.

Dr. PETER MACDONALD asked whether it was competent for practitioners to refuse—to use the word in the motion—this service to the new insurance group. The CHAIRMAN said that it was only competent for a practitioner to refuse all service.

Dr. A. BEAUCHAMP (Birmingham) asked whether it was competent for the Council to instruct practitioners to refuse service when the Panel Conference had accepted it. The CHAIRMAN said that in his view it was not competent for the Council to override the decision made by the Conference of Insurance Practitioners themselves. The present motion contained an inaccurate statement. It suggested that the present Conference had ascertained that the great majority of practitioners did not desire to include this new group on their lists.

After some further discussion the Chairman ruled the Cleveland motion out of order.

Dr. F. W. CHEESE (East Kent) brought forward a motion disapproving the extension of the panel system and deprecating action being taken by the Government on matters concerning the medical profession without first consulting the profession's representatives. He said that this extension was the latest instance of a raw deal for the profession. The Minister appeared to have been prevailed upon by powerful approved societies to surrender to their vested interest.

Dr. Cheese accepted a suggestion to omit the first part of his motion, and it was agreed to in the following form:

The Conference deprecates action being taken by the Government on matters concerning the medical profession without first consulting the profession's representatives.

Panel Committees not Adequately Informed

Dr. A. S. GOUGH (Watford) brought forward a motion expressing indignation that the Insurance Acts Committee had failed to keep local committees adequately informed during the recent vital negotiations. He complained that many representatives at the recent Panel Conference were not properly instructed by their committees. He himself waited for six months until in the first week of July he happened to notice the report of the I.A.C. meeting in the *Supplement*. He thereupon requested the summoning of an extraordinary meeting of his Division to discuss that report. That meeting decided to send a letter of protest against acceptance of the proposals, but this was held up until after the Panel Conference on July 31. There had been no real opportunity for instructions from the Panel Committees to be given. They paid their subscription to the Association in the belief that the Council would provide them with adequate information and leadership. Prominent members of the Association had expressed in letters and speeches their opinion as to the injustice of the present basic fee and the action of the Government, yet in spite of this no leading articles had been published in the *Journal* advising them to withstand this pressure, and vital information had been held up until it was too late for them effectively to discuss it. It was said that after the war the question of the capitation fee would be gone into "from the ground floor." Unless they reorganized themselves they would go from the ground floor to the basement, taking in all dependants up to £420 at a bargain basement capitation fee. This would involve practically a State service, and its control would remain in the hands of the approved societies.

Dr. J. A. PRIDHAM (Dorset) said that the Insurance Acts Committee had for many years been led by statesmen as opposed to politicians, meaning by statesmen those who took a broad national view, and by politicians those whose view was a party or class one. At Conferences such as the present and at Panel Conferences clashes had occurred between politicians and statesmen. There was a need for the leaders to educate the rank and file of the profession, or those leaders were liable to be replaced by people who would take a narrower view.

Dr. GREGG said that he was anxious that the utmost publicity should be given to everything that had taken place in the negotiations between the Insurance Acts Committee and the Ministry. He complained of the motion that a great deal in it was not true, and the part which might have a grain of truth was unhappily expressed.

Dr. GOUGH asked the Conference to pass the motion as an expression of the undercurrent of feeling which was evident in the Conference. The Council had a moral obligation to see that it was "contacting" the practitioner. It had miserably failed on this occasion to keep practitioners informed in time for them to express their opinion.

The motion was carried.

Dr. GREGG accepted a motion from Finchley which expressed regret that the negotiations had produced such a meagre increase in the capitation fee and urging the Association to take steps to ensure that the Government was held to its firm promise as to the reopening of the question after the war. Dr. T. A. CRAWFORD (Finchley) said that while the Council had recommended a 20% increase in private fees, the efforts of the Insurance Acts Committee had resulted in only an 8½% increase.

A further motion which combined two others was agreed to: "That the Government be requested to provide as an urgent necessity free medical attention for dependants of men in the Forces."

The CHAIRMAN ruled out of order, despite the protest of the representative, a motion by North-East Essex calling for the reference back of the recent national health insurance proposals in regard to the capitation fee and extension of income limit in order that they might be considered by the whole profession; he did so because of the vote of the Panel Conference.

Criticism of the Insurance Acts Committee

Dr. C. I. SCHIFF (City of London) moved a resolution expressing "complete dissatisfaction with the recent action of the Insurance Acts Committee in its negotiations with the Ministry of Health." If ever there should have been a plebiscite, he said, it was in this case; instead it had been handled in a semi-secretive way, with the result that the first battle with the Ministry of Health had been lost, and "when the bell rings for the second round we shall come up bruised, smarting, and discouraged." The general public had a notion that in a very quiet and easy way the general practitioner had secured a material advance in his rate of remuneration; this was entirely contrary to fact.

Dr. GREGG asked for the grounds of dissatisfaction. Were they dissatisfied because the committee had protested to the Minister against its action in including a new group of insured without consultation, or because it had said that it would not recommend his terms to a Conference, but would leave the Conference to determine the matter for itself, or because it had secured, along with a sum to meet the increased practice expenses and mileage, an absolute promise that the matter of the capitation fee should be gone into fully after the war and that legislation would be passed to make the new financial provision which a higher fee would necessitate? This "silly resolution" implied dissatisfaction with all these things. "Do not be foolish. Of course you are not dissatisfied with them. You are damned glad you have got them. You hope to get more, and we hope to get more for you." (Applause.)

Dr. BODMAN (Bristol) said that in his Division they were still dissatisfied; they felt that the protest to the Minister was not "tough" enough. Some of them were also of opinion that the Panel Conference did not express the feeling of the profession as a whole. It was arranged at such short notice that those who appointed the representatives had not time to make up their minds.

Dr. T. R. DAVIES (South-West Wales) opposed the motion. The best way to improve the standard of service was to bring in people of higher economic and social status.

Dr. C. G. TAYLOR (Norfolk) spoke of a growing volume of protest in his county, where there was a feeling that the officers of the Association came too much under the influence of the Ministry of Health.

Dr. F. GRAY (Wandsworth) said that it had been suggested that some doctors were prepared to refuse service under the new terms. He wondered whether the grounds for dissatisfaction were that the committee did not recommend all practitioners to refuse service. Did anyone suggest that in the middle of a war, when the country was fighting for its existence, the profession should go on strike?

Mr. P. W. L. CAMPS (South Middlesex) said that the majority in his Division were in favour of the extension. The opinion of

the lay public should also have some weight. At one meeting of lay persons in his constituency the opinion was wholly in favour of this extension.

Dr. HOWIE WOOD (Isle of Wight) said that the profession was not adequately consulted before action was taken.

Dr. SCHUFF said that he objected to the surrender because of the tempo which it would give to future discussions. There was no need for any representative to talk about a strike. If a plebiscite had been taken it would have announced to the Minister that a given percentage of practitioners were against the scheme, and arbitration might have been suggested. Even if arbitration had not been granted, the matter could have been so handled that their patients, instead of saying, "I hear you have got a rise, doctor," would have said, "Well, doctor, you have got a raw deal."

The City of London motion was carried by 71 votes against 56.

PROTECTION OF PRACTICES

Dr. H. D. MCLROY (Greenwich and Deptford) asked that the position of doctors who had left their practices to go to a reception area should be reviewed, and that those who had voluntarily left their practices to do similar work in "safe" areas should have the benefits of the Protection of Practices Scheme withdrawn from them. Such practitioners should not be permitted to draw a considerable financial benefit from the work of colleagues who had remained in the danger zone.

Dr. F. GRAY (Wandsworth) pointed out that in the reception areas it was no secret that there was a great shortage of doctors, and that young men eligible for the Forces had had to be left in practice because they could not be spared, while in other areas doctors were not overburdened with work. He thought that men who had left evacuation areas for reception areas were doing work of national importance.

Dr. C. HILL (Deputy Secretary) said that the full responsibility lay with Local Medical War Committees, but many committees had realized that it was in the national interest where a good case had been made out that transfers should be arranged. Speaking on a further resolution that the present 50-50 basis of sharing fees was inequitable, Dr. Hill said that the local areas could have varied the ratio before the scheme was adopted, but only one area had done so. In any case the schemes were legal agreements which could only be varied now by agreement of all signatories, including absentees. It might on the face of it seem unfair that no allowance for expenses was made to the acting practitioner; but in fact the acting practitioner could enjoy such increments of practice as were normally available, whereas the absentee practitioner, speaking generally, could only experience a wastage of practice without the compensating increment.

It was agreed to pass to the next business.

RECRUITMENT OF MEDICAL PERSONNEL

Dr. E. C. DAWSON (Derby) asked the Council to approach the appropriate authorities with a view to making it clear that the Central and Local Medical War Committees were solely responsible for the allocation of medical personnel for recruitment for the armed Forces and for all branches of the E.M.S. and civil defence. Dr. C. M. STEVENSON (Cambridge) said that there seemed to be a constant effort in some quarters to by-pass the Central Medical War Committee. Prof. PICKEN said that this motion by Derby was far too general to cover the particular difficulty. He objected to the word "solely." The Government had never handed over to any non-Government body the final responsibility in these matters. The committees were acting as agents of the Ministry of Health, which was itself acting as agent of the Ministry of Labour.

The Derby motion was agreed to after the elimination of the word "solely." A motion by Camberwell was agreed to drawing attention to the dangerous depletion of civilian medical provision and advocating the employment of part-time civilian practitioners for duty with isolated Service units as a contribution towards the solution of the difficulty.

Dr. N. A. SPURR (Hampstead) brought forward a motion deploring the attempt of the Central Medical War Committee

to coerce senior general practitioners to join the Forces while so many young practitioners were employed in the E.M.S., whose work could, to a large extent, be carried out by general practitioners. It seemed a prodigal waste of valuable manpower.

Prof. PICKEN said that the majority of the young men in the civilian hospitals were recent graduates who were putting in their agreed six months. They were not sheltering in the hospitals; they were getting ready to go. The problem in London was rather different from that of the Provinces. In London there were probably more practitioners than were actually required, but large numbers of them were retired or over military age, and it was impossible by the quota system to get them out for any other purposes.

Dr. C. W. SOMERVILLE (Lothians) said that in many cases it was the older men who should join the Forces rather than the younger men, for the work of the men at home was much harder than the work of the men in the Army in the last war.

The CHAIRMAN OF COUNCIL said that the Central Medical War Committee had this problem very much in mind, and would do everything in their power to find a solution.

The motion was withdrawn, and a further motion by Hampstead calling for the registration through the Labour Exchanges of all practitioners up to the age of 55 was lost.

ALIEN PRACTITIONERS

Dr. R. B. HICK (Swindon) had a motion recommending that increased facilities be given to refugee doctors to practise in this country for the duration of the war. In his area one refugee practitioner was serving in a shop and another was a private in the Pioneers, emptying railway wagons. It was not in accordance with the dignity of the profession that any member of it of whatever nationality should be so employed.

The SECRETARY (Dr. Anderson) said that last year two Orders were made, the first of which gave permission to Canadian and American doctors not registered in this country to practise here under certain conditions; the second, again under certain conditions, gave a similar permission to doctors from other Dominions, the Colonies, and certain European countries. They were required to produce credentials which were satisfactory to the General Medical Council, also to have passed the security test of the Home Office and its Aliens War Service Department, and the permission given them to remain in this country was only for the duration of the war. It was intended only that they should practise in hospital services or some service connected with civil defence. A number of medical men from other countries—Greece, Yugoslavia, and Egypt, for example—were excluded by the terms of the Order, but an Order was now on the stocks extending the number of countries, which were now to be referred to, not specifically, but as territories abroad. The Order of 1940 made it imperative that before a man could be registered he must have a job in view, but the new Order would permit registration before he secured the job. It was also to be permitted to such a practitioner, with certain safeguards, to engage in practice as an assistant. It was felt that it would not be right or fair to allow a foreign practitioner without a British qualification to engage in practice on his own account. The Central Medical War Committee had approved these new proposals as a wartime measure with the safeguards he had mentioned. The present motion was a little too wide. For example, a certain number of practitioners would not pass the security test, but they would all be covered by this resolution.

The Swindon motion was withdrawn.

OTHER RESOLUTIONS

On the motion of Dr. A. BEAUCHAMP (Birmingham) the Council was asked to request the Minister of Labour to reserve at least one maid in a doctor's house. Portsmouth had a motion that doctors' white coats and overalls should be procurable without coupons. The SECRETARY said that this had already been taken up with the Board of Trade.

Dr. H. S. PASMORE (Kensington) asked that the Association should adopt the Kensington scheme for providing facilities for continuous postgraduate study for general practitioners. The

scheme, he said, had two advantages. It enabled the practitioner to keep himself abreast of the progress of medicine, and it led to better co-operation between practitioners and hospitals. The CHAIRMAN said they were all in favour of postgraduate education, but it did not seem to him that at the moment they had sufficient leisure to organize courses. The Conference agreed to proceed to the next business. A further motion by Kensington that a general practitioner should be attached to the staff of every teaching hospital to instruct students in the art of general practice was referred to the Medical Planning Commission.

A resolution from East Kent asking the Association to endeavour to arrange for more medical representation in the House of Commons was agreed to. The same constituency asked that medical boards should be set up for women who are being called up for compulsory service in any capacity. The CHAIRMAN pointed out some difficulties in the way of this proposal, and it was agreed to proceed to the next business. A Camberwell motion that all institutions used as hospitals by local authorities should be, as a matter of compulsion, administered under the Public Health Acts instead of under the Poor Law was also referred to the Medical Planning Commission, and from the same constituency a motion urging the employment of part-time medical officers where practicable in the various local government services was agreed to.

Dr. J. A. PRIDHAM (Dorset) moved that the Minister of Health be requested to make scabies a notifiable disease. Prof. PICKEN pointed out that "notifiable disease" was a term with a very specific meaning. Measles and whooping-cough were not in law notifiable diseases; they were diseases which had to be notified, which was a different thing. He suggested that the motion should read: "... be requested to confer upon local authorities adequate powers and duties to prevent the spread of scabies." This might or might not include notification. In this form the motion was adopted.

On the motion of West Suffolk it was agreed that Divisions be urged to take action through the local press in their areas to popularize the use of the national wheatmeal loaf.

Compensation Payable to Practitioners

Mr. WELDON WATTS (Newcastle) moved:

That any doctor injured in the course of his duties as a member of a civil defence organization should be entitled to compensation at a rate not less than that of a captain in the R.A.M.C.

His Division considered that there was little difference between the civilian doctor carrying on his work under present conditions and his colleague in the Army.

The CHAIRMAN OF COUNCIL said that representations had been made in this direction on six occasions, and a Cabinet decision turned it down. The Cabinet saw no reason why they should be compensated save on the terms for men engaged in A.R.P. duties. He thought it a hardship that they were not treated as Army officers, but there the matter stood.

Dr. C. F. TURNER (Coventry) said that he was injured on his way to an "incident," and was told that for compensation he should apply to the Assistance Board. He did not proceed further with the matter, but he did not see why he should have any more compensation than his ambulance driver or the volunteers at the post. The only thing which differentiated the doctor was that he had to provide a locum tenens and most of the others did not. The whole status of civil defence was wrong, and until it was elevated to the rank of one of His Majesty's Forces under proper discipline and control and with proper allowances, pensions, and so on, there would be no satisfaction.

The motion was lost.

On the motion of Dr. MARK FRASER (Cumberland) the meeting unanimously sent

"a victory message to all Branches and Divisions asking for increased membership and more enthusiasm and loyalty so that at the end of the war the B.M.A. shall be a live body able to speak both for the medical profession and for the health and well-being of the nation."

The Conference concluded its work by passing a hearty vote of thanks to its Chairman.

BRITISH MEDICAL ASSOCIATION

109th ANNUAL GENERAL MEETING

The 109th statutory Annual General Meeting of the British Medical Association was held in the Great Hall of the Association's House, Tavistock Square, London, on Thursday, September 11, 1941. The PRESIDENT (Dr. Thomas Fraser of Aberdeen) was in the chair.

The SECRETARY read the notice convening the meeting, and the minutes of the Annual General Meeting held in London on October 28, 1940, were taken as read, approved, and signed as correct.

On the motion of Dr. J. C. A. NORMAN (Bournemouth), seconded by Dr. O. C. CARTER (Bournemouth), it was unanimously agreed:

That Messrs. Price, Waterhouse and Co. be and they are hereby appointed auditors of the British Medical Association until the next Annual General Meeting at a remuneration of three hundred guineas.

The TREASURER (Dr. J. W. Bone) moved that the statement of accounts of the Association as published in the *Supplement* of May 17, 1941, be received and approved. He said that the accounts were in a very satisfactory condition. The motion was agreed to.

Conferment of Gold Medal

The PRESIDENT announced that the Council at its meeting that day had awarded the Gold Medal of the Association to Sir Kaye Le Fleming, M.D., of Wimborne, in recognition of his distinguished work for the Association and the profession. He then proceeded to present to Sir Kaye Le Fleming the testimonial in respect of the award of the Gold Medal. In doing so he said that he wondered whether members of the Association appreciated the full extent of the services which were demanded from the occupant of the chair of the Council. Those services called for an extraordinary sacrifice of professional time and energy. He had had opportunities of watching the work of four previous Chairmen of Council—namely, the late Dr. J. A. Macdonald of Taunton, the late Sir Robert Bolam of Newcastle, Sir Henry Brackenbury, and Sir Kaye Le Fleming, and it was noteworthy that three of the four came from the Provinces, an appropriate circumstance in view of the fact that the Association itself was provincial-born, in Worcester in 1832. Each of these chairmen had borne a rather heavier burden than his predecessor as the duties attaching to the office had increased. On none of them did the mantle appear to hang so lightly as on Sir Kaye Le Fleming, and during his five years of chairmanship the Association had gained an enhanced reputation in the eyes of the public and the State.

Owing to gold restriction it was not possible at the moment to hand to the recipient the Gold Medal, but in the meantime the President handed to Sir Kaye the testimonial in respect of the award in the form of an illuminated book. This was done amid loud applause, all the members standing.

The meeting then terminated.

The following resolution was passed at a meeting of panel practitioners held in the rooms of the British Medical Association in Edinburgh on September 9: "That this meeting appreciates the action already taken by the British Medical Association in endeavouring to have introduced into national health insurance the dependants of insured persons, and, while keeping in mind this end, would in the present emergency urge immediate action for the inclusion of the dependants of men serving in His Majesty's Forces."

Correspondence

Medicine, Politics, and Economics

SIR.—The main reason for my last letter to you (*Supplement*, August 23) was to sound a note of warning to those members of the B.M.A. who needed it of the existence of a threat to the interests of the profession through the influence of party politics. It is well known that the frustration of the national and, to a lesser extent, the local electorates is due to this cause. This itself should have been sufficient to put us on our guard against the danger of political divisions in our ranks, but apparently it was not, since we now split our voice amongst the British Medical Association, the Medical Practitioners' Union, and the Socialist Medical Association. This undoubtedly is the chief cause of the ineffectiveness with which our "representatives" negotiate with the Ministry of Health and other authorities.

I am grateful to Mr. Aleck Bourne (*Supplement*, September 6) for removing from the S.M.A. the vagueness and mystery in which it appears to have left it enshrouded. I believe that nothing but good can come of bringing this association and its activities into the clear light of day. Perhaps Mr. Bourne will be good enough to tell us something about its history and present affiliations. In reply to the rest of his letter let me say that the picture which he paints of a tamed medical profession which takes its orders from the political party which for the time happens to be in power is not at all attractive to the majority of medical men.

In reply to Lieut.-Colonel S. H. Fairrie's letter (*Supplement*, September 6) may I say that I am aghast at his suggestion that the Medical Planning Commission has been set up simply to decide on what kind of State Medical Service we are to have thrust upon us. If the truth is anything like this the situation is indeed serious. I quite agree with him, however, that our present discontent has reached such a pitch that something must be done to improve matters, but in this I see no justification for throwing ourselves to be stamped into a position from which there is virtually no escape if found unsatisfactory, as if this were the only alternative to the present deplorable state of affairs. Under the circumstances might we not to begin with be more profitably employed in trying to find out why, during the last twenty-five years or so, conditions for the individual have been going from bad to worse? If we make the attempt, however, one thing we must not do is to accept "the wickedness of the average human being" or "the profit motive" as an adequate answer unless we can prove that one or other (or both) of these factors has reached a much greater intensity during this period than ever before in history. I am convinced that the correct answer is already known to a considerable number of persons and, furthermore, that publicity is disallowed in their own interest by certain powerful groups. At any rate, I submit, Sir, for your readers' consideration the following statement:

That the chief cause of our social and economic distresses is the progressively increasing centralization of irresponsible power (over persons) in the hands of fewer and fewer practically anonymous individuals, with a corresponding curtailment of the initiative of the common man, and the palming off of more and more centralization as the only cure for the evils which centralization has itself produced: hence the remark, "The question no longer is, Are the medical profession in favour of a State service? but rather, What kind of a State service are we prepared to accept?"

On the question of finance there is still a word which needs to be said. What the blood and its circulation are to the body, money and the money system are to the community. No matter what our theories, no matter what our religion—the life of every one of us depends on money. When the money system is found to be working unsatisfactorily for the majority of a community and it is decided to try to improve it, two problems have to be considered: (1) What are the modifications which must be made in order to achieve the desired result? This is a technical matter which our financial experts could deal with in a very short time after being given the order to get on with the job. It is, however, a matter of mere academic interest until the second problem has been solved, which is: (2) How can the opposition of those who use money and the present money system as a means to power on the grand scale be overcome? This is a political matter and

should engage the earnest consideration of every one of us immediately the war ends, if not before.

If any are sufficiently interested to write me and enclose a stamped, addressed envelope I shall be pleased to direct them to a wealth of information on these problems.—I am, etc.,

Cray House, Boxley, Kent, Sept. 8.

E. U. MACWILLIAM.

State Medical Service

SIR.—May I be permitted to join in the correspondence on the future of medicine. The correspondence is of vital importance and of great interest—important because it demonstrates an almost universal recognition of the desirability and inevitability of change; of interest because it shows how divided is the profession in its views on the type of change and the means of achieving it.

It seems to me that so many writers are losing sight of two things. First, our own interests do not come before those of our patients; they never have and never will, nor should they. They may come a good second, but in the formation of a medical service, whether State or otherwise, the greatest benefit of the greatest number of the public is the principal concern. Secondly, the health service (i.e., medical practice in all its aspects) is one of the essential services of the country. It behoves some members of the medical profession to take stock of some of the general social changes that are going on around them. We have too many ostriches in our ranks. What in the world are we fighting this war for? Surely not only to rid the world of Hitler, Mussolini, and their like, but to eliminate the causes of world chaos of which such men are but symptoms. Social injustice and insecurity, poverty and malnutrition, speculation and graft, vested interests and the financial oligarchy, usury and self-interest—these are but some of the causes of the present disaster.

Surely we can make a start by ridding our own profession of some of its ill-health. Vested interest in disease is an abomination: the whole system of loans and mortgages; the buying and selling of practices, which produces nothing but an economic millstone round the necks of so many doctors; the stranglehold of the friendly societies on insurance practice—are all things of which we could rid ourselves given sufficient unity of purpose. The health of the community, for which we claim responsibility, is too important to be mixed up any longer with the financial racket. Only general social legislation can remove the extra-medical causes of ill-health, but we can do much for our patients by our willingness to accept and aid such legislation.

A State Medical Service need not be such slavery as some of your correspondents would have us believe. It can be what we, the profession, choose to make it. As a scientific profession we are being remarkably unscientific in our criticisms and our applause. We should get down to scientific principles; examine by a purely fact-finding investigation our whole present lay-out; find out its weaknesses, requirements, and possibilities; and by real reorganization and planning of all aspects of medical practice, education, hospitals, general practice, specialization, and subsidiary services, etc., lay the foundations of a really efficient service. There is a great deal of self-interest and parochialism evident in some quarters. There is much apathy in all quarters. There are strong prejudices to be overcome. One of your correspondents, Lieut.-Colonel S. H. Fairrie (*Supplement*, September 6, p. 43), airily rejects Dr. R. S. Saxton's suggestion that we at least give thought to Russia's State service by saying that it is hardly opportune at this moment . . . that it might not suit us . . . so we had better leave the U.S.S.R. out of it. Ye gods! The one fully working, tried and tested, complete medical service in the world, and we are to leave the U.S.S.R. out of it—the system, as Mr. Aleck Bourne points out in the same *Supplement*, that has among other things produced a phenomenal decrease in the tuberculosis and infant mortality rates.

We cannot afford to sit back whilst the world changes round us. We shall find that we are one of the things that will be compulsorily changed without our having much say in the matter. Whether in a socialized community or in any other we should be in the van of social progress. I feel that, through lack of unity and constructive effort, we are in danger of being left behind.—I am, etc.,

Basingstoke, Sept. 10.

R. P. W. SHACKLETON.

SIR.—The spate of letters on the advantages of a State Medical Service may delight the younger generation who have had no experience of panel practice and who have invested no capital in a general practice. It may be, too, that the Socialist members of the profession see at last their Utopia in sight. To those of us, however, who are not Socialists and who wish to retain our individuality and who have been quite a number of years in a general practice which we have no desire should be confiscated, such a scheme is anathema. It is well that this fact should be known.—I am, etc.,

London, N.W.1, Sept. 14.

RUSSELL STEELE.

SIR.—What does the profession really think of the light-hearted way in which some of your correspondents are writing off its vital liberty of thought and action?

A definite day off every week, regular holidays, fixed salaries and pensions far outweigh trust, friendship, professional freedom, and initiative, in the estimate of many of our brethren. Lack of business acumen and of bedside manner, and diffidence in money matters are given as some of the evils which dog the medical man and are to be removed by a State Medical Service.

Can anyone seriously believe that a practitioner who treats his patient with reasonable skill and care cannot keep simple accounts and present and render bills? State control may make the practitioner's life easier, but the standard of his work will inevitably deteriorate, to the detriment of the patient and the good repute of the whole profession. The introduction of national health insurance cannot be said to have raised either the reputation or professional standard of the general medical practitioner, and I cannot see how a State Medical Service can do anything but lower these.

Medical planning generally is a job for the public and the profession after the war, the winning of which should be absorbing all our energies.—I am, etc.,

Windsor, Sept. 13.

J. M. McINNES.

SIR.—So much has been said and written of late in regard to the future of medical practice that I hesitate to trespass upon your limited space. But I ask leave to get out of the dark forest that we now seem in danger of being lost in, into the open, so that we may review the position calmly and dispassionately. It occurs to me that State Medical Service to be or not to be must be considered first from two aspects—namely, (1) the point of view of the general public; (2) the point of view of the medical profession as a whole.

To attempt to answer for (1) may seem hazardous, but I do believe that we, foremost among the nations of the world, are a nation of individuals. I believe that were the entire adult population of the United Kingdom asked to reply to a brief questionnaire containing two questions—for example, (a) Do you and your family desire to be attended as private patients by a doctor of your own free selection? or, (b) Would you prefer yourself and your family to be attended by a whole-time salaried State official?—an overwhelming majority would reply in favour of (a). Almost everyone wishes to be a private patient. The thing that worries millions of people is how to pay their medical expenses. How to raise the money is the point, not how to be attended. It should be simple to devise an insurance scheme by which this could be done. It seems lunacy that the entire medical profession should be sold or surrendered into bondage rather than face the position and evolve a satisfactory insurance scheme. Something on the lines of the National Deposit Friendly Society could undoubtedly be devised for all.

(2) At the end of the war I believe that the medical profession, just like the lay population, will look forward to regaining their freedom and to returning to civil life as free individuals, to their own way of life and their own free individual way of doing things, to their homes, their families, and their work. All those who feel confident in their own ability will desire to resume work as private individuals: 8,000 to 10,000 doctors liberated from the Forces will look forward to regained freedom; those freed from the E.M.S. and other not particularly satisfactory services and systems of the world war will also desire to be free; this is to say nothing of the almost universal discomfort felt by thousands of practitioners with the present panel system and inadequate capitation fee and with the heartless, soulless Ministry.

May I say once again that 90% of post-war medical work will still be general practice, and most of this will be mixed class—panel and private practice. The bulk of the general practitioner's work is bound to be very much as hitherto, a very small proportion of which represents clinical entities.

No State Medical Service should be considered unless it embraces every medical man or woman on the Medical Register. Specialists should be "debunked," their work being auxiliary, not that of super-men, the general practitioner being quite as much a "specialist" in his own sphere. Anything less than this would be simply to split the profession into two classes—an immeasurable disaster. But a most necessary first stage would seem to be an extension of and improvement in the N.H.I. scheme.—I am, etc.,

CHARLES A. H. FRANKLYN, M.D.

Hurstpierpoint, Sussex, Sept. 12.

Future of the Profession

SIR.—I have read with sinking heart and flagging interest the numerous articles and letters in the *Journal* anent the future of medicine. From this chaos emerges the fact that there is an appalling lack of unanimity and clear thinking in the profession.

When I am in a quandary I endeavour to make use of specialized experience: a schoolmaster for my children; a solicitor if I am involved in the law; a specialist when I am out of my depth with a patient. Surely a similar method should be applied to the immensely more important matter of our future professional existence?

I therefore suggest that:

(1) An institute of applied psychology be employed to make a comprehensive survey of medical practice, and to make recommendations in the light of their findings.

(2) That upon these data we base our deliberations.

(3) That an experienced political adviser be retained to present our conclusions to the Government.

(4) That a successful propaganda agent be employed to (a) enlighten, within the limits of professional decorum, the public—who require our services; (b) bring our views pointedly to the notice of our respective members of Parliament—who require our political support.—I am, your very depressed member,

Swinton, nr. Manchester, Sept. 9.

J. H. MOORE.

Payment of Deputies and Assistants

SIR.—It is to be regretted that no medical body exists which has the willingness and the ability to bring some semblance of order into the chaos of fees and salaries offered to locums and assistants.

Recent numbers of the *Journal* show that members of the profession value the services of their less fortunate colleagues at anything from £350 to £1,000 per annum. The former sum was actually put forward for an outdoor engagement. Personal experience has taught me that some doctors are willing to pay only seven guineas a week for the services of a locum. In peacetime I expected to pay more for a reliable man.

Furthermore, £50 per annum appears to be looked upon as a more or less standard allowance for a motor-car. One wonders how many doctors in Great Britain would be satisfied if their local inspectors of taxes allowed them only £50 as their motor-car expenses, apart altogether from the wear and tear clause.

The gentlemen who are lucky enough to require assistants but who want to secure them at the lowest possible prices might be reminded that with income tax at its present level they are trying to get their less fortunate colleagues to serve them at a cost to themselves actually less than would have been the case before the war. Their wretched employees would, of course, have to pay income tax on the present high rates and thus have a much smaller net income than formerly, despite the fact that the pound now has a very greatly reduced purchasing power in every other field.

Equity seems to demand that the assistant should be paid a living wage, and that over and above this he should receive some sort of bonus or share in the extra earnings of the practice which he is helping. As a stimulus to discussion one would put forward a suggestion that the first charge on the earnings of the practice should be the profits of the principal in the last year before the

war. Thereafter the assistant's salary—say £350 indoor, £450 outdoor—would be debited. The balance of increased profits should be divided between the two parties in proportions to be decided by an actuary.

It is absurd that a profession which is so jealous of its financial rights *vis-à-vis* any outside employer should permit extreme niggardliness within its own ranks.—I am, etc.,

DONALD O'CONNOR.

"Pure Despotism"

SIR.—Dr. T. T. Apsimon (*Supplement*, August 30, p. 37) would appear to have enjoyed complete immunity from "despotic officials" in his practice of panel medicine. He scouts the notion that such officials ever existed, and assumes that the bulk of the profession would display considerable hilarity at the mere mention of such a possibility.

It is a fact that not only has the professional life of many doctors been made miserable on account of "despotic officials," but also it is not outside the bounds of truth to suggest that even tragedy may have occurred either directly or indirectly from the bullying of such officials. From my own personal experience I may say that I was for years subjected to bullying: if it was not bullying, then words have lost their meaning. That part of my professional life which was connected with panel practice was made worse than miserable, and by intent. I was then much younger than I am now and did not know that the N.H.I. Act had no spirit, but only the letter. I conceived the idea that the practice of medicine had relation to the investigation and treatment of disease, together with its study. It needed many years to convince me that such affairs had no place in the N.H.I. Act. What mattered most were the forms and ceremonies, the sanctified funds of the approved societies, and, particularly, certain dates on the calendar. For my peace of mind I became a conformist. As in Russia, about which country Dr. Apsimon seems to be so well informed, so in the United Kingdom, to be a non-conformist means the nearest thing to extinction. My feelings are still bitter, and the passage of years has not made them any less bitter. An Act which might have been so beneficial, which might have been the means of advancing medicine, has been so mishandled, so subjected to the ignorant obstinacy of "despotic officials" (among others) that after thirty years of action it has practically nothing to recommend it from the clinical standpoint.

What composes this mighty State to which so many doctors would hand themselves over? I forbear to provide the answer. Dr. Lindsey W. Batten in his admirable letter (*Supplement*, August 30, p. 36) writes: "It has been my constant experience that the State does not want my best work, does not really like it, and very frequently has stood between me and the doing of it." I concur heartily with Dr. Batten. Many truths about the N.H.I. Act have appeared in your columns since the correspondence first commenced upon the subject. This is the most fundamental truth of all. Its substance should be examined by the Medical Planning Commission. But the purpose of this Commission will, I fear, not be made manifest until it is accomplished.—I am, etc.,

Schry, Yorks, Sept. 7.

J. C. GILLIES.

Organized Representation: Appeal for Union

SIR.—Of late there have been many letters of complaint about this, that, and the other, the underlying—often unwritten—grumble being that no matter what we decide among ourselves no Government body is going to take much notice. Well! Why should it? At the present moment we have more than one representative body, each supported by a proportion of our number and each with views often differing considerably from those of the other. Were there only one body and that supported wholeheartedly in its policy our present invidious position would alter. Now each of these bodies maintains that it serves the profession, aided by our subscriptions. Would it not be real service if they met together, determined that, though perhaps many members of each council might by their own actions become redundant, one amalgamated body should be formed, whose composition and policy would have the support of the entire profession, and able, therefore, to command attention. Each one of us will have his own ideas as to the constitution of this amalgamated body, my own view being that numerically

proportional representation would be a very good thing for a change.

Such a meeting having taken place (with, I trust, wide professional publicity) confined solely to broad issues with all personal feelings sunk, each as yet individual body should circularize its members, acquainting them of the mode of discussion, and the basic proposals made, with a card vote. His Majesty—if not H.M. Government—would, I feel, give permission for the Service members to take part in this. The scheme is vast, requires much individual thought, yet, as our daily work involves the solution of problems no less intricate, not impossible.

Might I also take this opportunity of pointing out that should the profession, as at present represented, be forced into an unsatisfactory service, the next generation of the great British public—including the children of the individuals composing the present Government—will find that their doctors are not, as now, physician cum friend cum lawyer cum parish priest, but strange scientists behind a counter, even assuming that the best type of brain has any desire to practise medicine from behind a grille.—I am, etc.,

Stamford, Lincs, Sept. 15.

A. HENRY GREGSON.

* The recent Conference of Representatives of Home Divisions of the B.M.A. (reported in the *Supplement* this week at page 59) passed a unanimous resolution calling for "increased membership and more enthusiasm and loyalty so that at the end of the war the B.M.A. shall be a live body able to speak both for the medical profession and for the health and well-being of the nation."—ED., B.M.J.

Doctors at First-aid Posts

SIR.—I read with regret the letter of "Medical Officer, F.A.P." in the *Supplement* of September 13 (p. 47). It radiates that spirit of defeatism which seems so prevalent in the profession at present.

By all means let the medical officers be relieved of administrative work, if they have any. The administration in my own post has always been carried out most efficiently, at first by the Red Cross commandant, and latterly by the sister, and I gather that this system obtains in the other posts round about. But when it comes to training, then I submit this is a matter for the medical officer alone, backed up, as he will be, by the trained nurse. Why should B.R.C. or St. John officers or lay superintendents do what is most properly our job? And, for that matter, if we are to give up teaching first aid, where are these officers to receive their instruction? Does not the word "doctor" mean "teacher"?

I have been giving instruction in first aid over a period of thirteen years, and can assure "Medical Officer, F.A.P." that there is no better way of learning than by teaching. Our post has become a centre of instruction, where all connected with Civil Defence are cordially invited. Three times a week for at least one hour per visit this is given by the medical officer, and daily by the sister. Lectures are given (particularly on the wartime aspects of first aid), team tests are arranged and judged, practical first aid taught, and oral questions asked—the last, by the way, being very popular, and a great help to those studying first-aid manuals.

Let the A.R.P. medical officer keep to the administrative side; but let the doctor (that is, general practitioner) give the instruction with all the wealth of sympathy and understanding which goes with general practice.

I say only this about fees. If the three visits a week are truly and conscientiously made, then £75 per annum is a cheap price for the help given and knowledge imparted to the first-aid personnel.—I am, etc.,

GILBERT R. HULL,
Medical Officer in Charge,
First-Aid Post No. 6.

Streatham, S.W.16, Sept. 13.

Equipment of Home Guard First-aid Posts

SIR.—It is difficult to understand the reason for the lack of facilities Home Guard medical officers have to contend with in obtaining the necessary equipment for the collecting places to which Home Guard casualties may be taken should an emergency arise. They are expected as part of their duties to find suitable places for the purpose, and, having done so, are left wondering through what channel they can get all they may require to make

the first-aid services given there as thorough as they are intended to be. Are the first-aid workers in the Home Guard, or any M.O. who may be called upon to render such services, expected to do so without or with extremely limited equipment? This state of things would be as unfair to them as it would be prejudicial to the well-being of the unfortunate men who may need urgent help in circumstances the nature of which no one can foresee.—I am, etc.,

Greenhithe, Sept. 15.

D. W. STANDLEY.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

ROYAL NAVAL VOLUNTEER RESERVE

Acting Surgeon Lieut.-Commander W. J. Heely to be Surgeon Lieutenant-Commander.

Probationary Temporary Surgeon Lieuts. F. A. Shackleton, R. J. Ingham, J. L. Burnet, E. L. Mommen, G. M. Watson, F. R. Aston, A. C. Hamer, N. A. Douglas, and R. P. Strang to be Temporary Surgeon Lieutenants.

ROYAL ARMY MEDICAL CORPS

Temporary Commission.—Major P. N. Creagh has relinquished his commission and retains the rank of Major.

Short Service Commission.—Captain A. F. Murray forfeits nine months' service for the purposes of promotion.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major A. Badenoch has relinquished his commission on account of ill-health and retains his rank.

Second Lieut. C. C. Laird, from Royal Artillery, Territorial Army, to be Lieutenant, next below Lieut. J. D. F. Norman.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel G. C. E. Simpson, O.B.E., T.D., having attained the age limit, has relinquished his commission.

Captain A. R. Ward, having attained the age limit, has relinquished his commission.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Major St. G. E. Harris, O.B.E., from temporary commission, to be Lieutenant.

War Substantive Captains A. A. M. Roberts, P. O'Driscoll, and T. T. Stocker have relinquished their commissions on account of ill-health.

ROYAL AIR FORCE

Flight Lieut. J. H. Lewis has been granted a permanent commission in the substantive rank of Flight Lieutenant.

Mrs. Edna V. Butler Jones has been promoted to the relative rank of Flight Lieutenant (War Substantive).

Miss Lesley I. Stewart has been granted a commission for employment with the Royal Air Force with the relative rank of Flying Officer.

ROYAL AIR FORCE VOLUNTEER RESERVE

To be Squadron Leaders: N. Black and E. M. Darmady.
Flight Lieut. D. H. Le Good has relinquished his commission on account of ill-health.

To be Flight Lieutenants: S. W. Liggett and R. C. Morton.

The notification in the *London Gazette* dated February 18, p. 1087, column 1, concerning E. C. de M. Morgan should have read "Flight Lieutenant" and not "Flying Officer."

Flying Officers P. J. M. Kent, J. H. Hurt, H. F. S. Beadles, W. J. Lawrence, W. J. O. Page, C. K. Cole, J. M. Jones, P. H. Denton, and W. M. L. Turner to be Flight Lieutenants (War Substantive).

To be Flying Officers: G. W. Bellis, G. H. Boston, M. F. J. Clarke, J. L. Connor, E. H. L. Cooke, G. H. Cooper, A. Craig, J. M. Dawson, J. M. Ferguson, J. E. Gilbert, A. H. Hands, E. N. Jenkinson, D. U. MacDonald, R. E. Glennie, A. M. P. Laurent, J. J. O'Callaghan, G. O. Richardson, W. D. Roden, L. B. Scott, C. R. Sluning, J. A. Sutton, T. G. Band, A. L. Bell, T. B. Binns, J. G. Burgess, C. A. Forssander, M. L. Gaudin, J. Harper, N. W. Horne, J. B. Lowe, D. H. Meldrum, J. F. Rickards, H. D. Ross, T. B. Russell, G. A. Summers, H. M. Urquhart, W. S. Whitting, G. M. Wilson, I. M. Wood.

INDIAN MEDICAL SERVICE

Lieut.-Colonel S. N. Makand has retired.

EMERGENCY COMMISSIONS

To be Lieutenants: R. T. Hinde, P. S. Clarke, E. L. Jones, D. G. Horan, T. D. Brown, P. N. Swift, W. Thomson.

REGISTRATION OF DOCTORS' MAIDS

We printed in the *Supplement* of August 2 (p. 18) a letter which the British Medical Association had sent to the Ministry of Labour asking for more consideration to be given in individual cases to the transfer of doctors' maids under the Registration for Employment Order. A reply has now been received from the Ministry. After stating that the procedure has been under review, the Ministry writes:

"I am to inform you that the most important change in the new procedure is to delay calling for interview women registered under the Order until their employers have been consulted. Any representations which the employer may make will be given careful consideration, and full account will be taken of the importance of the work on which a person is engaged, the actual nature of the work which the person is doing, and the possibility of replacing young women by older women. Where local offices are satisfied that releases should be made and substitutes should be provided they are instructed to give the employer every assistance possible to find such substitutes and not to effect any withdrawals until they are satisfied either that the employer is refusing to engage suitable substitutes or that he is not making reasonable arrangements to enable the work to be undertaken by substitutes."

POSTGRADUATE NEWS

The Fellowship of Medicine announces that a practical operative surgery course on the cadaver will be given for Final F.R.C.S. candidates at the Royal Cancer Hospital on Mondays, Wednesdays, and Fridays, at 2 p.m., from October 6, for three to four weeks.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE: 10 a.m. to 4 p.m., Clinics and Operations, Obstetrical and Post-mortem Demonstrations. *Mon.*, Course on War Medicine commences. *Tues.*, 10 a.m., Paediatric Clinic, Dr. R. Green. *Wed.*, 10 a.m., Sterility Clinic, Mr. V. B. Green-Armistage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*Calcutta Hospital*, The Hyde, N.W.: *Thurs.*, 2.30 p.m., Final F.R.C.S. Urology Course. *Royal Cancer Hospital*, *Daily*, 10 a.m., Final F.R.C.S. *Radcliffe Infirmary*, Oxford: *Daily*, 9 a.m., Course in Anaesthetics.

CENTRAL MIDDLESEX COUNTY HOSPITAL, Acton Lane, N.W.—*Thurs.*, 3 p.m., Dr. W. Pagel: Demonstration of Some Cases in Pathological Department of the Hospital, 1939-41.

GLASGOW UNIVERSITY: Tennent Institute, Church A. J. Ballantyne: *Thougl* —At Prof.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of History of Medicine.—*Wed.*, 3.30 p.m. Papers by Sir Walter Langdon-Brown: John Caius and the Revival of Learning; Dr. H. P. Bayon: Paracelsus and the Rosicrucian Romantic Legend.

Section of Physical Medicine.—Oxford, *Sat.*, 12 noon, Demonstration of Cases by Prof. H. J. Seddon and Dr. B. Kiernander at Wingfield Morris Hospital; 2.30 p.m., President's Opening Remarks; 2.45 p.m., Demonstration of Cases and Film on the Treatment of Burns, including the Use of Movement and Short Wave, Surgeon Lieut.-Commander J. Bunyan at Radcliffe Infirmary; 4.15 p.m., Demonstration of Electrically Induced Convulsive Therapy by Lieut.-Col. Armstrong.

B.M.A.: Branch and Division Meetings to be Held

NORTHERN IRELAND BRANCH.—Joint meeting with Ulster Medical Society at Whitla Medical Institute, Friday, October 3, 5 p.m. Sir Joseph Barcroft, F.R.S.: A Gas Attack: What to Do, and When to Do it.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than five post Monday morning to ensure insertion in the current issue.

MARRIAGE

MACLEOD—KOTZE.—At Greenside Parish Church, Edinburgh, by the Rev. D. S. Hopkirk, on September 20, 1941, Tormod, youngest son of Mr. and Mrs. Kenneth Macleod, The Rectory, Fortrose, to Cecilia Johanna, youngest daughter of the late Mr. Sari Kotze and Mrs. Kotze, Vredendal, Cape Province, South Africa.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 4 1941

WAR NOTICES

E.M.S. Payment for Radiologist's Report

It will be remembered that when the Ministry of Health announced the rates of payment for Class III practitioners in the E.M.S. it was stated that the fees payable to a radiologist or pathologist for special investigation and report within the scope of his specialty and without examination of the patient by the specialist in clinical charge of the hospital would be on a scale which was being drawn up in consultation with the Central Medical War Committee. The fees for the services of radiologists have now been agreed; they will operate as from September 1, 1941, and are set out in the Ministry's latest circular (No. 2478) as follows:

Group No. 1.....7s

Extremities: one area
Foreign body: detection of
Teeth: one area

Group No. 2.....14s.

Extremities: two areas	Salivary glands
Pelvis	Urinary tract: plain
Spine: one area	Abdomen: plain
Teeth: more than one area	Gall-bladder: plain
Upper or lower jaw	Foreign body: localization of

Group No. 3.....21s.

Extremities: more than two areas	Oesophagus
Chest	Barium meal
Bronchography	Barium enema
Tomography	Cholecystography
Myelography	Sialography
Skull	Urography (intravenous or ascending)
Accessory nasal sinuses	Pregnancy
Mastoid and petrous temporal	Pelvimetry
Ventriculography	Cephalometry
Encephalography	Salpingography.

The Ministry points out that the arrangements in paragraph 5a of Circular 2394 concerning the fee payable to physicians or surgeons or other medical officers in clinical charge of patients remain unchanged. Agreement has not yet been reached on the scale of fees payable to pathologists.

Uniforms for Doctors at First-aid Posts

A circular (No. 2492) is being issued by the Ministry of Health to local authorities and their medical officers on the subject of uniforms for doctors at first-aid posts. After consultation with the Ministry of Home Security and the Central Medical War Committee, it has been agreed that doctors allocated for service at first-aid posts should be reckoned as senior officers in the Civil Defence First-aid Post Service, and may be supplied by the local authority with the appropriate uniforms—namely, for men, serge battledress, greatcoat, beret, boots, and leather anklets; for women, serge jacket and skirt or trousers, greatcoat, felt hat, and leather shoes. The circular continues:

"Arrangements will be made in due course for supplying the shoulder title '1st Aid Post' as in the case of other members of that service (see paragraph 7 of Home Security Circular No. 189/41), and in addition a special shoulder title with the words 'Medical Officer' to be worn immediately below the shoulder title of the service. The practitioners in question will be allowed to wear their uniform in the same manner and subject to the like conditions as those prescribed for other senior officers in paragraph 11 of Home Security Circular 189/41.

"The issue of uniforms authorized by this circular should be limited to the practitioners shown on Section 1 of the quarterly returns of First-aid Post Personnel (Form E.M.S. 125) made to Senior Regional Officers of the Ministry, and is not authorized to other practitioners who may be included in the emergency lists of practitioners prepared by medical officers of health."

CENTRAL MEDICAL WAR COMMITTEE,
B.M.A. House, Tavistock Square, W.C.1.

COURSE FOR HOME GUARD M.O.s

[FROM A CORRESPONDENT]

The course, which was held at Cambridge from September 11 to 16, was an outstanding success. When it was arranged at the request of the War Office and the Central Medical War Committee by the D.D.M.S. II Corps it was intended to limit the number of medical officers taking part to thirty. Some 150 applications were received, and in the end thirty-eight took the course, which, by the courtesy of the Master and Fellows, was held in St. John's College. The D.D.M.S. had arranged an intensive programme of lectures and demonstrations, and the enthusiasm of the members, undeterred by continuous work, including both Saturday and Sunday, continued to show itself in syndicate discussions on Home Guard problems far into each night. This programme was designed to give these medical officers, many of them veterans of one or more campaigns, not only a conspectus of the modern treatment in the forward areas of wound, burn, and gas casualties, but also a background of the latest medical and combatant views on "total" warfare, air attack, armoured combat, and chemical warfare, as well as guidance on the diverse and constantly growing duties assigned to the Home Guard. Every subject was dealt with by the appropriate specialist officers, including staff officers of high rank, and a standard of lecturing prevailed which a long experience of lectures suggests was extraordinarily high. Despite an average of some seven lectures or demonstrations each day the interest of the members never flagged, but was perpetually rekindled by the infectious enthusiasm and obvious mastery of his subject displayed by each successive lecturer. Of the more strictly medical subjects, those on war surgery in the forward areas and the medical aspects of chemical warfare were naturally of outstanding interest where all were of the best. Military discipline prevents the mention of the names of any of the military lecturers or the details of the syllabus, but there are certain features to which reference can be made.

On the afternoon of arrival those attending the course were welcomed by the Master of St. John's, Mr. E. A. Bennions (Vice-Chancellor of the University), the President, and other Fellows. The Master in his welcome gave a graceful summary of St. John's medical record, its succession to the Hospital of St. John with its infirmary; the Linacre tradition; and the great medical men who had been members of the College, such as Sir William Gilbert, President of the Royal College of Physicians and physician to both Elizabeth and James I. Of particular interest to Home Guard medical officers was Sir Isaac Pennington, Regius Professor of Medicine as well as Linacre Lecturer, who, at the age of 60, in the threat of invasion by Napoleon I in 1803, raised the first Cambridge University Volunteers, commanding the St. John's Company of forty-six men, with the great Lord Palmerston, then a youth of 19, and Hugh Martin, the celebrated missionary, as his ensigns. Major-General Lord Loch also welcomed the members and urged the paramount need of the Home Guard for training and sustained enthusiasm and vigilance. Prof. H. A. Harris, professor of anatomy in the University, gave the course a stimulating lecture on the teaching of first aid, packed with aphorisms and good things, thoroughly unorthodox and so most useful to the medical officer, whose own original ideas on teaching first aid have become somewhat formalized from long and

hard wear; especially was this lecture useful as it was generally agreed that it was desirable that every man in the Home Guard should receive some simple teaching in the elementary principles of first aid. A striking historical corrective was given by the President of the College, the Rev. M. P. Charlesworth, who lectured on the medical arrangements of the Roman Army, illustrating *inter alia* first aid from Trajan's Column; and plans and details of military hospitals. The latter, with their cubicles and small two- and four-bed wards, spacious corridors, wide courtyards, and *thermae* for balneotherapy, anticipated modern hospital planning in many ways.

The rehabilitation of the substandard recruit, hygiene, mess-tin cookery, the latest devices for removing wounded are samples of the "diversity of gifts" presented to the course. But every subject was presented in a way which broadened the outlook of the Home Guard medical officer, for as the pace of warfare becomes faster so medical aid in the forward area becomes more difficult and its methods must perforce be simpler and more self-reliant. A visit was paid to a field hygiene section, and demonstrations were given of the latest field-hygiene and water-purification devices that will be of great service in the many isolated posts which Home Guard detachments may garrison. The organization of the Home Guard medical service was the subject of several lectures and of many lively syndicate and general discussions. On the final evening the course had the honour of a particularly heartening address by the Corps Commander, who, paying tribute to the fighting spirit of the Home Guard, emphasized the need in its medical service for the closest and most tactful co-operation with the Civil Casualty Services.

At their last evening's discussion the members of the course passed a unanimous resolution to express their thanks and appreciation to the War Office and the Central Medical War Committee for arranging this course; to the Master, President, and Fellows of St. John's College, Cambridge, for allowing them the use of the College; to the D.D.M.S. II Corps, and the Commandant; and to the lecturers. They expressed the hope that other courses on similar lines may be arranged from time to time.

INSURANCE OF HIGH-FREQUENCY APPARATUS

In the *Supplement* of September 21, 1940, we explained why it was necessary, for reasons of national security, for private practitioners to surrender their high-frequency apparatus to the General Post Office during the war. Recently the owners of impounded apparatus have been informed by the General Post Office that they are responsible for paying an insurance premium under the Business Scheme of the War Damage Act in respect of the apparatus. As the imposition of this liability upon practitioners who had already been deprived of a considerable part of their means of livelihood seemed most unjust, the following letter of protest was sent by the Secretary of the British Medical Association to the General Post Office:

"My attention has been drawn to a circular letter which you have issued to medical practitioners who have surrendered high-frequency apparatus to your Department in accordance with the recent Order prohibiting the use or possession of such apparatus except in certain approved institutions.

"Practitioners have loyally responded to the call made upon them, although this has invariably involved a considerable financial sacrifice and, in some cases, the loss of the doctor's main source of income. It is, therefore, with surprise and regret that I read your statement that the insurance of the impounded apparatus under the War Damage Act is entirely the responsibility of the owner. I am unable to understand why the Post Office authorities, having seriously prejudiced a doctor's means of livelihood by compulsorily removing an important part of his professional equipment, and having stored this equipment in some instances in vulnerable areas where air raids are likely to be of frequent occurrence, disclaims responsibility for insuring against the risk of its destruction.

"It is conceivable that this attitude is strictly in accordance with the provisions of the War Damage Act, but I cannot think that any court would uphold such an arrangement as equitable. In my opinion it is indefensible, and, on behalf of this Association, I wish to protest strongly and to ask that the position be reconsidered as a matter of urgency. I shall be glad to have your observations at your earliest convenience."

The following reply has now been received:

"With reference to your letter of September 5 to the Engineer-in-Chief of the Post Office, I am directed by the Postmaster-General to explain that the Control of High Frequency Apparatus Order, 1940, was made by the Home Secretary for reasons of national security.

"In view of the Order, the retention of high-frequency apparatus by the practitioners to whom you refer would have been an offence under the Defence Regulations, and the apparatus was consequently taken into the custody of the Post Office as an alternative to its destruction, with a view to its return when the Order ceases to be operative. Neither the Post Office nor any other Government Department obtains advantage from the arrangement, which is essentially different from that of requisitioning property for use by the Government.

"The Postmaster-General is a bailee of the apparatus and is under the usual obligation to take proper care of it, but this does not include liability for damage caused by enemy action or other causes beyond the Postmaster-General's control. The apparatus is usually stored in premises where Post Office electrical apparatus is kept, and which are in most cases probably better able to stand bombardment than a private house.

"In the circumstances the Postmaster-General regrets that he is unable to assume responsibility for insurance or for any war damage which may unfortunately occur to any of this apparatus while it is in his custody.

"The circular letter to which you refer has been sent out to enable and assist owners of apparatus which has been damaged or destroyed by enemy action to be in a position to put forward claims under the War Damage Act. The Post Office will, of course, be ready to give any further necessary assistance in individual cases."

The Council of the B.M.A. is considering what further steps shall be taken.

Correspondence

Doctors at First-aid Posts

SIR,—The letter signed "Medical Officer, F.A.P." (*Supplement*, September 13, p. 47), shows such extreme lack of psychological insight, both in regard to the doctors and the personnel of first-aid posts, that a protest seems called for. Your correspondent says: "... there is no necessity for the doctor to have any administrative power nor to have any work of training"; and later: "... there would be no necessity for medical officers in charge of first-aid posts to put in routine visits at all." Has he never heard of team work? How does he imagine that the personnel (most of them voluntary and non-professional) will react during a "blitz" to the ill-understood demands of a complete stranger? How does he imagine the doctor is to know which of the staff he can trust to apply a Thomas splint (probably none if only St. John or B.R.C.!); which will keep their heads as receptionists; which is suited to act as dresser to himself—unless he has trained them and knows their characters and capacities? Further, how is a strange doctor to know the layout of his post (since the majority of first-aid posts are makeshift buildings), the little snags which have to be overcome, the equipment—what is supplied as standard and what must be supplemented, where the stretchers will go, and when trigglift must be used? Does he really imagine that a stranger can take hold successfully and inspire the confidence and sense of steady leadership without which a first-aid post or any other unit is merely a collection of individuals? In this matter, at least, the Central Medical War Committee has exercised more imagination than your correspondent.

And surely we are not so sordid that the pay offered for this national service becomes a major issue. Most first-aid post doctors began to train their teams before the outbreak of war; at that time the retaining fee was £20. Did not most of them work just as hard then as now? And do they regard £75 as the value of their services? I hope and trust that I am speaking for the great majority of first-aid post doctors when I say that if the Government choose to do so they may cut our fees altogether and we shall still carry on the work to which we have set our hands; but that if they ask us to leave the training of our teams to strangers we shall refuse and, if necessary, resign.—I am, etc.,

YORK, SEPT. 15

J. C. LYTH.

State Medical Service

SIR.—I have, I fear, invited Dr. Neustatter's rebuke (*Supplement*, September 20, p. 56) by rashly entering a controversy in which, so far as I can see, chapter and verse cannot be given for conclusions that may none the less be well founded, and generalizations are unavoidable. I am glad of the chance to agree, fully and gratefully, that the London school medical service allows its medical officers full freedom to do their allotted tasks in their own way, to form their own judgment and express their own views; nor is "red tape"—the multiplication of forms and petty restrictions—the worst evil I foresee in a State service, though I think it may be a real one. What I fear most is the half-heartedness, the timidity, the unreality which I still think are characteristic of a great deal of clinical work directed by the British democratic State as we actually know it. A State Medical Service may indeed be administered by medical men—though it will probably be agreed that good doctors do not in general make good administrators—but controlling the administrators must inevitably be a Ministry and a Minister, Parliament, and behind Parliament the Press and all manner of associations of the public, ignorant of science and of the very nature of clinical medicine, credulous in some respects, suspicious in others, and, as we have good reason to know, with little love for our profession. Instead of being answerable, in the main, to our patients and our consciences we shall be answerable to Parliament and the public, and the fear of the "question in Parliament" will come filtering down until it reaches us with its chilling and stultifying touch in our clinic or wherever it be decreed that we shall work. I still believe that it will be a bad day for the profession of medicine and for our patients when we are one and all gathered in to a State-controlled medical service.—I am, etc.,

London, N.W.3, Sept. 20

LINDSEY W. BATTEN.

Extension of Health Insurance

SIR.—In the numerous letters which have appeared in the *Supplement* on the proposal to include persons with an income up to £420 per annum, no one so far seems to have grasped the real crux of the situation, which is a political and financial move by the approved societies to maintain their incomes. These incomes must be suffering severely for two obvious reasons: (1) their younger, presumably healthy, members are all in the Army and furnishing no contributions; (2) the high rate of wages prevailing at this time has raised many of their members well above the present income limit of £250 per annum, thus causing an additional loss of contributions. The first situation is beyond their control, so they have made use of the second, which involves a class who are the backbone of better working-class private practice and pay standard fees willingly. Moreover, this group, earning about £420 per annum, will certainly be made up of men above 45 years of age whose incidence of disease is found to be high, consequently requiring considerable medical attention. This fact, combined with the loss of the young healthy men at present in the Army, warrants an increased capitation fee; but one naturally asks why this proposed change was permitted without consulting the profession.—I am, etc.,

"OBSERVER."

Health and Preventive Medicine

SIR.—Dr. E. Granger's letter (*Supplement*, September 20, p. 56) cannot be allowed to remain unanswered. To one who believes that preventive medicine will be the medicine of the future the statements in the latter half of his letter, which, incidentally, have nothing to do with the problem of a State Medical Service, are amazing.

Dr. Granger obviously does not understand the meaning of health-consciousness, which implies not only a desire for health but an undertaking on the part of the individual that he or she will, for health's sake, try to observe the rules of health. For far too long the medical schools of this country have been turning out doctors whose conception of health was merely the absence of recognizable disease. The difference between the latter negative condition and the state of optimum or positive health is not easily understood by those who have never experienced "the joy of being alive." The State can never give to the people

positive health unless they are willing to co-operate or are, in other words, health-conscious. The individual cannot escape his own fundamental responsibility for the care of his health. The development of health-consciousness is one of the encouraging signs of the times, and its promotion should certainly be a main aim of the school medical service. It is a sad but true fact that this new conception of health as something positive at which to aim is, among the majority of doctors, conspicuous by its absence. Health-consciousness could only be the forerunner of neuroses if it were accompanied by complete ignorance of the laws of health, and the two conditions are never likely to occur together.

Dr. Granger then states that "preventive medicine can go much too far." It certainly can if, as he suggests, tonsillectomy and circumcision be included within its scope! Finally, his statement: "I do not believe that prevention is necessarily better than cure," is an opinion in which, I trust, few doctors would be willing to concur. For if that view were generally held the future of medicine would indeed be dark.—I am, etc.,

Plymouth, Sept. 22.

JAMES HARPER.

CERTIFICATES FOR EXTRA MILK

The Council of the B.M.A. is pleased to report that as a result of its representations to the Ministry of Food the form of certificate for the supply of extra milk for invalids has been revised in a manner which, it is believed, will be acceptable to the profession. It will be remembered that the two main points at issue were the infringement of professional secrecy involved in handing a medical certificate to a dairyman and the schedule of diseases. The Association's protest with regard to the former has been met. Except in the case of diabetes, to which a specific reference is necessary for administrative purposes, practitioners will not have to name the disease from which the patient is suffering; they will only indicate the category in the schedule in which the case falls. The certificate will be sent to the local Food Office, where it will be dealt with by a special officer. The Association also suggested to the Ministry a number of improvements and additions to the schedule of diseases and the inclusion of sick children who are not attending school. These suggestions have been incorporated in the new schedule. The Council has expressed to the Ministry its appreciation of the way in which its criticisms and suggestions have been met.

Medical Forces of H.M. Services
Appointments

ROYAL NAVY

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Temporary Surgeon Lieutenants J. C. Jones and D. L. Cooke to be Temporary Surgeon Lieutenants.

ARMY

Colonel W. B. Rennie, M.C., late R.A.M.C., and Colonel (Temporary Brigadier) W. Bisset, M.C., late R.A.M.C., having attained the age for retirement, retire and remain employed.

Lieut.-Colonel (Temporary Colonel) N. Cantlie, M.C., from R.A.M.C., and Lieut.-Colonel E. A. P. Brock, from R.A.M.C., to be Colonels.

ROYAL ARMY MEDICAL CORPS

Majors (Temporary Lieut.-Colonels) L. B. Clarke and J. C. Denvir to be Lieutenant-Colonels.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel (Brevet Colonel) J. F. O'Grady, T.D., from R.A.M.C., Territorial Army, to be Colonel. (Substituted for notification in a *Supplement* to the *London Gazette* dated May 26, 1939.)

Lieut.-Colonels W. R. Ward, A. McK. Reid, C. H. Budd, and H. A. B. White Locke, all from R.A.M.C., Territorial Army, to be Colonels. (Substituted for notifications published in *Supplements* to the *London Gazette* dated May 2, 9, and 26, 1939, and July 11, 1939, respectively.)

Major H. J. A. Longmore, late R.A.M.C., T.F., to be Colonel. (Substituted for the notification in a *Supplement* to the *London Gazette* dated May 5, 1939.)

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Major W. Parsons, from Temporary Commission, to be Lieutenant.
Captain K. T. Goldswain has relinquished his commission.
Lieutenant J. Kelvin has relinquished his commission on account of ill-health.

ROYAL MALTA ARTILLERY

Williams, J. W.: *Obstetrics: A Textbook for the Use of Students and Practitioners*. Eighth edition, by H. J. Stander. 1941.

Correction

In the report of the Conference of Representatives of Home Divisions in the *Supplement* of September 20 (p. 50) Dr. L. Kilroe was stated to have withdrawn a motion on behalf of the Preston Division. Dr. T. H. C. Derham was the representative of Preston, and he withdrew the motion referred to.

B.M.A.: Meetings of Branches and Divisions

BERKS, BUCKS, AND OXFORD BRANCH

At the annual meeting of the Berks, Bucks, and Oxford Branch, held at Oxford on July 16, the following officers were elected for the ensuing year:

President, Dr. F. G. Hobson. *Vice-President*, Dr. S. F. Logan Dahne. *Honorary Secretary*, Dr. W. Arnott.

Sir ARTHUR HURST gave an address on "Mythical Maladies." After excluding extinct diseases, such as chlorosis, from the scope of the lecture, Sir Arthur then disposed of some bogies. He said, for example, that movable kidney produced no symptoms; "dropped stomach" was long stomach and physiological; gastric flatulence was due to air swallowing; duodenal ileus was not a cause of vomiting, and should not be treated by operation; intestinal kinks and adhesions rarely produced symptoms and were best dealt with medically; toxæmia was a myth; intestinal symptoms arose much more from purgatives than from constipation; and that mucous colitis did not exist, visible mucus being due to constipation, purgatives, or irritation by enemata.

A good discussion followed, and on the motion of Dr. LOGAN DAHNE, seconded by Dame LOUISE MCLROY, a hearty vote of thanks was accorded Sir Arthur Hurst for his address.

SUSSEX BRANCH: WEST SUSSEX DIVISION

At a meeting of the West Sussex Division, held at Worthing on August 22, with Dr. R. H. WILSHAW in the chair, Prof. J. A. RYLE gave a lecture, which was illustrated by slides and pictures, on "The Treatment of Gas Casualties." In the discussion which followed many questions were asked and the lecturer gave helpful answers. There was a large attendance, including dentists and nursing sisters who had been invited to be present. The meeting closed with a vote of thanks to Prof. Ryle for his address.

POSTGRADUATE NEWS

The following courses of lectures, etc., will be given at the London Homoeopathic Hospital, Great Ormond Street and Queen Square, W.C.: Thursday, October 9, at 2.30 p.m., introductory lecture by Dr. T. G. Stonham; Mondays and Thursdays, at 2.30 p.m., October to March, homoeopathic materia medica and therapeutics by Dr. C. E. Wheeler; Fridays, at 2.30 p.m., October to December, Compton Burnett Lectures on homoeopathic philosophy and prescribing by Sir John Weir; Fridays, October to March (autumn session 3.30 p.m., winter session 2.30 p.m.), tutorial class by Dr. D. M. Borland; Mondays and Fridays at 2 p.m., clinical tutorials by Dr. W. W. Rorke.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Clinical Section.—Fri., 2.15 p.m. Meeting at Westminster Hospital.
Section of Orthopaedics.—Sat., 2 p.m. Meeting at Horton Hospital. Short papers by Mr. H. L. C. Wood, Dr. L. Minski, Mr. J. H. Kellgren, Mr. E. J. Radley Smith, and Dr. C. D. Langton. Clinical cases and x-rays of interest, demonstrations of special cases and physical treatment. Members of the Section of Surgery are specially invited to attend.

CHADWICK TRUST.—At Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, W., Tues., 2.30 p.m. Mr. V. Zachary Cope: The Influence of War on Surgery.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—At Tennent Institute, Church Street, Glasgow, Wed., 8 p.m. Prof. W. J. B. Riddell: The Evolution of Postgraduate Study.

APPOINTMENTS

EXAMINING FACTORY SURGEONS.—C. L. Lander, M.B., B.S., for the Maiden Newton District (Dorset); W. Paris, L.R.C.P.&S.Ed., for the Alyth District (Perthshire); C. S. Wise, M.B., B.S., for the Sandwich District (Kent).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

MARRIAGE

D'ARCY—GOURLEY.—On May 12, 1941, at Lahore, Punjab, India, Captain T. M. W. D'Arcy, R.A.M.C., to Hester Hilary Gourley, Q.A.I.M.N.S.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 11 1941

THE ASSOCIATION'S GOLD MEDAL

The following is the text of the bound and illuminated address handed by the President to Sir Kaye Le Fleming when conferring upon him the Gold Medal of the British Medical Association at the Annual General Meeting held on September 11, 1941, as reported in the *Supplement* of September 27 (p. 66):

TO SIR KAYE LE FLEMING
M.A., M.D. (Hon.), M.B., B.Ch.

The Council of the British Medical Association, recognizing the continuous and valuable contribution which, during many years of service, you have made to the interests and prestige of the Association and to the influence and status of the medical profession, welcomes the opportunity to confer on you the highest distinction within its gift and to award to you the Gold Medal of the Association.

That this decision of the Council is in accord with the opinion and wish of the general membership of the Association is made manifest by the suffrages which have on repeated occasions elected you to positions of high distinction and large responsibility. These include, within the Association, the Chairmanship of the Representative Body during three years, and the Chairmanship of the Council from 1934 to 1939, while, by the choice of the general body of the profession, you presided over the Conference of Local Medical and Panel Committees from 1925 to 1929, and since 1928 you have been one of the Direct Representatives of the profession on the General Medical Council.

These elections and appointments carry a clear message of the confidence which your colleagues in various constituencies have placed in your judgment and capacity, and it is widely recognized that in all these offices you have provided both inspiration and guidance and have given liberal time and attention to the details of practical administration. In all these directions a large contribution to success has been the assurance of your unflinching loyalty, sincerity, and impartiality, and a recognition of your skill in the art of practical politics; with authority you have freely accepted responsibility, and while attentive to all the arguments you have practised a prompt capacity for the virtue of decision.

The occasion does not admit a detailed examination of all your activities within the Association, but there are two aspects of these on which a word may be allowed. First, on occasions not a few you have been called upon, and particularly as Chairman of Council, to represent the Association in public or semi-public, social or intraprofessional functions; and again, in more severe service, to negotiate and discuss legislative and administrative proposals with representatives of His Majesty's Government and other public bodies. Each of these engagements has its own claim and opportunity, and on the verdict of your fellow representatives you have ever proved equal to the event and have secured a presentation of the Association worthy of its status and traditions.

Secondly, it is to be observed that while maintaining a high level of interest in the general administrative service of the Association, you have applied a particular attention to developments which offer to the medical profession an opportunity to apply its specialized skill and knowledge to the general welfare of the community, and this both in the prevention of disease and also in the promotion of health. Medicine, you have recognized, is in its widest application a mode of social service which aspires to contribute to the welfare, efficiency, and happiness of the whole body of the people. Particularly in the work of the

Association's Committees concerned with Nutrition and with Physical Education you have provided both enthusiasm and direction, and have thus at one and the same time recognized a professional obligation and served well the cause of public policy. That these services have received official recognition is a welcome event to the profession generally, and particularly to those who have been associated with you in various public offices and responsibilities.

Not without interest it may be noted that the services you have so generously rendered to the Association and the profession have been contributed while you have been engaged in active medical practice some distance from London. That the discharge of these official claims must have involved much personal sacrifice is obvious; such a record has happily many precedents in the annals of the Association, which, representing as it does all the interests of the profession, properly welcomes to its service all the talents.

In adding your name to the list of the Association's Gold Medallists the members of the Council discharge a pleasing duty and responsibility. At the same time they offer to you a cordial assurance of their affectionate confidence and sincere regard, and they welcome your continued and active co-operation in circumstances which claim in special measure the gifts of wisdom, of experience, of courage, and of good will.

THOMAS FRASER,
President.

H. GUY DAIN,
Chairman of Representative Body.

H. S. SOUTTAR,
Chairman of Council.

JOHN W. BONE,
Treasurer.

MEDICAL WAR RELIEF FUND TWENTY-THIRD LIST

Previously acknowledged £32,740 2s. 9d. and £100 3s.
Conversion Stock and £40 3% Defence Bonds

Individual Subscriptions

- 45.—Dr. C. G. Morrice, Wellington, N.Z.; Dr. F. D. Woodhouse, Blandford St. Mary.
43 3s.—Dr. R. McIntosh, Sherborne.
42 12s. 6d.—Dr. R. S. MacArthur, Stourport.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Plymouth East (Devonshire) is vacant. Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by October 21.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than five post Monday morning to ensure insertion in the current issue.

BIRTH

TRIPP.—At 23, Park Circus, Glasgow, on September 28, to Barbara (née Thomas), the wife of Squadron Leader Christopher Howard Tripp, a son.

DEATHS

KERR RUSSELL.—On October 5, 1941, at the Radcliffe Infirmary, Oxford, William Kerr Russell, M.D., husband of Eleanor Kerr Russell, M.D. (née Wylam), late of 126, Harley Street and 75, Gayton Road, Harrow, and only son of the late Dr. Frank Russell of Newcastle-upon-Tyne. Temporary address, Duxmete House, Ross-on-Wye.

ROBERTS.—On April 21, at St. Peter Port, Guernsey, Charles Leonard Digby Roberts, M.B., Ch.B., D.T.M.&H., at the age of 59.

THOMAS.—On Sunday, September 21, at Redbrook-on-Wye, William John Thomas, M.R.C.S., L.R.C.P., D.P.H., beloved husband of Beatrice Mary Thomas, late of 3, King's Gardens, Hove.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 18 1941

DOCTOR'S CONSCIENTIOUS OBJECTION

A Borough Council's Action

The following letters have been sent by the Secretary of the British Medical Association to the Ministry of Health and to the Town Clerk of Dudley, respectively, concerning the action of the County Borough Council of Dudley in suspending its medical officer of health for the duration of the war because that officer had registered objection to military service on conscientious grounds.

From the Secretary of the B.M.A. to the Ministry of Health

October 8, 1941.

I enclose a copy of a letter which has been sent to the County Borough Council of Dudley declining to accept for publication in the *British Medical Journal* an advertisement for a temporary Medical Officer of Health to fill, for the duration of the war, the post now held by Dr. McLennan, who has been suspended by his Council for the duration of the war on account of his exercising his rights under the section of the Military Service Act dealing with conscientious objection.

The Association, of course, offers no observation on the conscientious objection of Dr. McLennan. It does, however, protest most strongly against the action of the Dudley County Borough Council in taking a step which is in direct conflict with the wishes of the Government and, as we believe, of Parliament.

It is a matter of considerable regret to the Association that the Ministry of Health has found itself unable to intervene in order to prevent a local authority from victimizing an officer of high repute and recognized efficiency and from depriving the local community of the services of a skilled and experienced officer.

Dr. McLennan has done no more than exercise his rights as a citizen, and the Association feels that it would be contrary to the public interests to help the Dudley County Borough Council to secure a substitute for the duration of the war.

It is hoped that, even at this late stage the Minister will reiterate to the Dudley Council the Government's view in the matter and use his influence to bring this suspension to an end.

From the Secretary of the B.M.A. to the Town Clerk, Dudley

October 8, 1941.

I refer to the advertisement for the post of temporary Medical Officer of Health and School Medical Officer submitted for publication in the *British Medical Journal*.

After careful consideration the British Medical Association has reached the conclusion that it would be contrary to the public interest to publish this advertisement and so to invite medical practitioners to make application for a post from which the present holder is to be suspended solely because he registered as a conscientious objector. In reaching this conclusion the Association has had in mind the following statement by the then Prime Minister, the late Mr. Neville Chamberlain, when moving in the House of Commons the second reading of the Military Training Bill and speaking with particular reference to the sections of the Bill relating to the machinery for considering conscientious objection:

"I want to make it clear here that in the view of the Government, where scruples are conscientiously held we desire that they should be respected and that there should be no persecution of those who hold them. All we have to do is to see that they are not abused, and to try to provide for these special cases of people who are not prepared to undertake the ordinary combatant service but wish to do national service of one kind or another."

It is clearly the Government's desire, expressed on this occasion and subsequently in governmental communications to local authorities, that there should be no victimization of those whose scruples in regard to military service are conscientiously held. To facilitate the appointment of a successor to a Medical Officer of Health who has done no more than exercise his legal rights as a citizen would, it is clear, be acting in conflict with the desires of the Government.

Further, in the prevailing serious and growing shortage of medical personnel in this country it would be a waste of skilled man-power, and contrary to the public interest, to suspend on such grounds a key officer of recognized experience and efficiency, and to endeavour to fill his post for the duration of the war from a very restricted and relatively inexperienced field of applicants.

The Association is conscious of the implications of its decision, and I am to ask your authority seriously to consider whether the public interest and the expressed desires of the Government, that there should be no victimization of those whose conscientious scruples lead them to avail themselves of their legal rights to register as conscientious objectors, do not require that the matter should be reopened and the decision to suspend the present Medical Officer of Health reconsidered.

I should be grateful if you would place this letter before your Council.

GENERAL PRACTICE

Changing Economic Conditions

A meeting of the General Practice Executive Committee of the British Medical Association took place in London on September 30, Dr. H. W. Pooler presiding. The principal business was the consideration of resolutions regarding the economics of general practice passed at the recent Conference of Representatives of Home Divisions. Some time was spent in considering a memorandum from the Ministry of Pensions setting out proposed scales of fees to practitioners serving on Medical Boards set up by the Ministry. This was in response to an expression of dissatisfaction with the rates hitherto prevailing which had been sent to the Ministry by the committee at its last meeting. The scales now submitted had been framed on the basis of the sessional fees agreed by the Association with local authorities. A careful examination was made of the new proposals, and certain detailed criticisms were put forward for submission to the Ministry.

Public Medical Services: The New Income Limit

A discussion took place on the possible effect on Public Medical Services of the new income limits for National Health Insurance. These services are, in general, available for the dependants of insured persons and others of like economic status, and inquiries have been received whether their rules should be modified in view of the raising of the salary maximum for National Health Insurance to £420 per annum. The recommendation to raise private fees by 20% also has its repercussions on Public Medical Service finance. The matter was referred to the Public Medical Services Subcommittee, a meeting of which is to be called as soon as possible.

The Increase in Private Fees

It was reported that advice had been asked of headquarters, following upon the recommendation to increase private fees by 20%, concerning the application of this increase to remuneration in respect of life assurance examinations, the National Deposit Friendly Society, and work done for local authorities and other bodies. A resolution on this subject at the recent Conference will be remembered.

On the subject of fees paid in respect of life assurance examinations it was agreed to recommend the main committee that a letter be sent to the central organization representing the life offices, opening up the matter of an increase, based, as in all these cases, on the increased cost of carrying on practice. The case of the shipping companies, the Post Office, and the prison service was discussed. It was pointed out that the resolution of the Council recommending a 20% increase in fees was intended to apply to fees received in private practice. It was

the view of the committee that part-time service of Post Office doctors and of district medical officers should be increased on the same basis, but the larger question of the remuneration of doctors by local authorities, apart from payment per item of service, should be the subject of later consideration after these other matters had been tackled.

Certification

Several resolutions from the recent Conference dealt with this subject. Some of the discussion in the committee centred round the question of certificates for exemption from fire-watching. The feeling was that the doctor should be expected only to make a statement—that, for example, the person was suffering from a certain disease or infirmity—not to give an opinion as to whether or not he was capable of fire-watching or any other service. One suggestion was that medical referees should be appointed for this purpose, on whom the onus would rest, though this would not prevent a doctor from giving a certificate in a case in which he desired to do so, and the certificate in that case would go to the referee. The same applied to certification in connexion with certain other matters, such as billeting and the Transfer of Work Order.

It was also urged that doctors should be relieved of certification with regard to matters in which medical knowledge and experience were not necessary, as, for example, in connexion with the supply of milk for young children. One member of the committee pointed out that the question of certification required looking into as a whole, and that it would make the position worse if for some form of certificate people had to go to the doctor, and for some other form, which to the patient at least was similar to the first, they were not allowed to go to him.

The views on certification which have been strongly represented are to be put forward to the appropriate authorities in a conference to be held shortly.

Reservation of Maidservants

Since a resolution on this subject was passed at the Conference, the Ministry of Labour has informed the Association that the procedure of calling registered women for interview under the Employment Order is to be delayed until their employers have been consulted, and that any representations which the employer may make will be given careful consideration.

Finally, the committee agreed to take up again with the appropriate authority the question of anaesthetics under the Dental Benefit Regulations. Where the insured person insists on having his own doctor to act as anaesthetist and the doctor charges a higher fee than that provided for in the scale, the dentist is responsible for paying the difference out of his own pocket. A suggestion that the insured person be allowed to pay the balance up to a certain maximum has so far not been accepted.

EMPLOYMENT OF OVERSEA DOCTORS

Reference was made in the *British Medical Journal* last week (p. 520) to the Medical Register (Temporary Registration) Order (No. 2), 1941, and to the amendment of Defence Regulation 32B, under which this Order has been made. The new Order takes the place of the Medical Register (Temporary Registration) Orders, 1940 and 1941. The provisions of the 1940 Order, which concerns only British subjects and American citizens holding American or Canadian diplomas, remain unchanged. Such practitioners should make direct application to the General Medical Council (66, Portland Place, London, W.1.) for temporary registration, and, if they are American citizens, they must obtain permission from the Aliens Department of the Home Office (P.O. Box No. 2, Bournemouth) before accepting civilian medical employment.

The original 1941 Order empowered the General Medical Council to register temporarily certain other practitioners holding foreign diplomas, provided that they were legally entitled to practise in certain territories specified in the Order. As has already been explained, the revised Order applies to all territories without limitation, and a person who has passed the examinations necessary to obtain a diploma will now be treated as if he held that diploma. An applicant for registration is no longer required to show proof that he was entitled to practise.

The new Order also extends the field of employment by permitting a temporarily registered practitioner to work as an assistant to a practitioner who is registered in the *Medical Register* otherwise than by virtue of the Defence (General) Regulations, 1939. *Temporary registration does not entitle a practitioner to engage in private practice on his own account, to conduct a single-handed practice as a locum tenens, or to continue in any form of medical employment after the present emergency has come to an end.*

Employment as an assistant in private practice must be arranged in consultation with the Central Medical War Committee, which is responsible for ensuring that the prescribed conditions are fulfilled. Oversea practitioners who wish this form of employment should communicate with the Committee at B.M.A. House, Tavistock Square, W.C.1, whether or not they have already obtained temporary registration. In no circumstances may they accept assistantships until the approval of the Committee has been obtained. Practitioners who propose to employ assistants with overseas qualifications must notify the Central Medical War Committee, which will supply names of candidates if desired.

Alien practitioners who already hold permits for employment in approved hospitals, institutions, or services "not involving attendance on patients in their own homes" are not required to submit their police registration books for fresh endorsement. The police authorities are being informed by the Home Office that the permit is now to be regarded as covering approved assistantships in private practice.

A recently published statement that registration may now precede selection for approved employment was made as a result of a misunderstanding, and is incorrect.

Before the 1941 Order was revised, the employment of ship surgeon on British ships had been approved for the purposes of the Order. Practitioners interested in this work are invited to communicate with the Central Medical War Committee, which is occasionally asked by Shipping Companies to nominate candidates.

Correspondence

State Medical Service

SIR.—I have read most of the letters concerning a State Medical Service with interest, though not necessarily with agreement, and should like to make some statements and suggestions.

1. Having been in a Colonial Medical Service I can bear out the member of the Highlands and Islands Service that a State Medical Service is not necessarily bureaucratic, and that it does not necessarily interfere with the practitioner's methods and initiative. I therefore write off those who make this assertion as unreliable witnesses.

2. There is an undoubted case for making the benefits of medical science more readily available to the public. This can be done in part: (a) by making diagnostic facilities directly available to the G.P. without the intervention of a specialist or hospital out-patient department; (b) by grouping consulting and waiting rooms into health and welfare centres, to which dispensaries and "clinic" facilities might be added; and where (c) adequate clerical help would be available, so as to let the doctor spend his time doctoring and not clerking.

3. The basis of any future hospital policy should be the "local general hospital." This must be big enough and busy enough for the local "general specialists" to keep their hands in, and to earn their bread and butter. There is no need for the local general hospital to affiliate with any one teaching centre. I know of one that has contacts with six teaching centres, with the result that it gets a better deal than it would get from any single one of them.

4. I am now in a local authority service, and find that my patients and I can treat each other as human beings, that treatment can be ordered without fear of overtaxing the patient's purse, and thus losing me a patient and the portion of my livelihood he provides. I therefore suggest that the formation of *ad hoc* "health and welfare" authorities, to operate the existing local authority services and the national health insurance services,

and to supervise the hospital services, deserves very careful consideration.

5. Personally, I consider that it is high time that the dependants of insured persons were dealt with under the national health insurance service. This would mean that a great deal more work would be placed upon the profession, enough, if my sum is correctly done, to give employment to another twenty thousand doctors.

6. Whatever happens, the payment of panel practitioners on a salary-cum-capitation fee basis merits investigation. The salary would be paid by the *ad hoc* authority, who would decide how many doctors were needed in the area, and would rise by annual increments. Each doctor would still have his panel, and the value of each card on that list should rise by annual increments. It would thus pay the doctor to keep his patients—a direct incentive to good work.

7. The Ministry or Department of Health would remain in much the same position that is now held by these bodies.

8. Finally, there should be no need to consider the possibility of having a scheme we don't like being thrust upon us provided that we present a solid front and refuse to accept service. If the thousands of insurance practitioners were to refuse to treat the latest addition to the ranks of panel patients, no Government could force them to. Mind you, Sir, I am not advocating such a course just now. Union is strength, but if we do not stand together we shall get what we deserve—rule by the bureaucrats with red tape.—I am, etc.,

Seascale, Cumberland, Sept. 24.

I. C. MONRO.

SIR.—The pros and cons of State Medical and general practitioner service have been fully expounded by your correspondents, but the essential question of how best to prevent and cure has largely been obscured by the personal preferences of the general practitioner and the hypothetical preferences of the general public. I gather that most general practitioners (may I include myself?) prefer their way of life, which, in spite of hard work and hard knocks, is well loved; but do those cases where diagnosis is in doubt or specialized treatment required always go, and at once, to that place where the specialized knowledge required is available? And is that confidence which a majority of our patients undoubtedly repose in us really due to our skill or to their ignorance? And if our patients do not wish for any change in the present arrangements, is it not equally true that tight lacing, shut windows, and "dummies" were once held in high regard?—I am, etc.,

Potters Bar, Sept. 27.

W. E. HAYES.

SIR.—When first I joined the medical staff of the Ministry of Health I met the late Sir James Leishman, then chairman of the Scottish Board of Health, and he greeted me with this remark: "And so you have become an official and ceased to be a man!" May I commend the import of this cryptic utterance to the consideration of those advocates of a State Medical Service who would, for a mess of pottage, sell the individual liberty of our profession.—I am, etc.,

Harrogate, Sept. 29.

A. FULTON.

SIR.—The discussion in your columns on the subject of a State Medical Service prompts me to put forward the following questions, the answers to which seem to me to call for some consideration before we commit ourselves to a definite policy.

Does our experience of the working of Civil Service departments and of the operations of private enterprise lead us to suppose that the former is more efficient, expeditious, and economical, or vice versa? Are solicitors, accountants, stockbrokers, as a class intelligent and honest men, proposing to give up their individuality and merge themselves into State legal, State accountancy, or State stockbroking services? And, if not, do they know what is good for them and for their clients? Is our experience of national health insurance practice and our present treatment by the Ministry of Health such as to encourage us to put our affairs still more under ministerial control? Does not "Timeo Danaos et dona ferentes" still apply? And is not the increase in the capitation fee much the same colour as the Trojan horse? Lastly, while we probably all agree that the service of the medical profession to the public leaves much room for improvement, can we not set our own house in order without putting our trust in "Princes"?—I am, etc.,

Southbourne, Hants, Sept. 27.

T. M. BELL.

"Liability" for Health Insurance

SIR.—One of my patients recently informed me of the following facts, which may have some interest to practitioners in connexion with the extension of N.H.I. to include persons whose incomes lie between £250 and £420 per annum. He is a fairly well-to-do farmer, who, like several of his colleagues, holds a part-time appointment connected with the sugar-beet industry, carrying a salary in the neighbourhood of £400 per annum. He was recently sent the familiar brown medical card with instructions as to how to choose a doctor, and he has the appropriate amount for N.H.I. contributions compulsorily deducted from his monthly cheque. His reaction to what he felt to be a gratuitous interference with his private affairs was to pop the card into his waste-paper basket, and he says this reflects the attitude of his colleagues, some of whom have incomes making them liable for £1,000 to £1,500 per annum in income-tax!

It would appear that the test for eligibility for N.H.I. benefit is not a total income below the £420 mark, but any single item of income below that figure. If this is the case (and it must be unless the circumstances I quote arose through some official's misinterpretation of the rules), then I am sure that the indignation of these new and unwilling entrants to N.H.I. will be well matched by that of their medical attendants.—I am, etc.,

Norwich, Sept. 29.

E. G. WATSON.

* Insurable employment under the N.H.I. Act includes any single non-manual employment remunerated at a rate not exceeding £420 per annum for whole-time service. No account is taken of private income or income from other employment. If the employment is part-time the decision rests upon whether the rate of remuneration for whole-time employment would exceed £420 per annum. It is surprising, however, that deductions have already been made from the farmer's salary, as the Act does not come into force until January, 1942.—ED., *B.M.J.*

"Pure Despotism"

SIR.—My experience of insurance practice has been directly contrary to that of Dr. J. C. Gillies (*Supplement*, September 27, p. 69). In thirty years I have met not despotism official, have prescribed what I liked, and wasted as little time as anybody on the useless—that is, non-clinical—side of record keeping. This I am convinced has been the experience of the scores of colleagues I have associated with, for I never heard any really serious complaint of tyranny under N.H.I.

Doubtless there have been occasional cases of injustice, but nothing to justify wild talk about "pure despotism." Had there been, there would have been far more complaints from doctors, and there have been very few. Indeed, we are witnessing now from considerable numbers a demand for not less but more State control. A large minority (or is it a majority?) of the profession seems now to be in favour of a State service.

Dr. Gillies appears to be violently prejudiced against the whole N.H.I. Act. Yet when one remembers working-class practice before the Act and the old club system there is no doubt that it represents an advance. It has been an immense boon, giving some security against sickness to the working class. It has raised, not lowered, the practice of the G.P. Few now would wish to scrap it and go back to the old conditions. It has worked fairly well perhaps because it has retained free choice of doctor and has been mixed with private practice, so competition and the old family practitioner relationship have remained. And yet among the conditions of a State service unanimously approved by North London practitioners (*Supplement*, September 13, p. 45) free choice of doctor was not included. Where do the interests and wishes of patients come in?

There seems to be a good case for State action in regard to the hospital service for the provision of smaller local hospitals, clinics, etc. Here, as in the case of working-class practice, private enterprise has been inadequate. But whatever system of medical service may be chosen, domiciliary medical practice will bulk largest, and will be such work as is done now under N.H.I.: for the most part tedious, trivial, routine, requiring patience and physical and mental endurance on the part of practitioners. Patients will still want free choice of doctor. It is in their interest that this should be retained, and with it the competition and financial inducement for which, for such work, no satisfactory substitute has so far been found.—I am, etc.,

Bradford-on-Avon, Sept. 27.

T. T. APSIMON.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

Surgeon Lieut.-Commander S. Jenkinson to be Surgeon Commander.
Surgeon Lieut. D. Shute to be Surgeon Lieutenant-Commander.
Surgeon Lieut. M. G. Peever (Emergency) to be Surgeon Lieutenant-Commander (Emergency).

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Surgeon Lieut. A. W. N. Oatway to be Surgeon Lieutenant.

Probationary Temporary Surgeon Lieuts. F. M. Fea, R. D. Royds, D. M. Armstrong, A. C. Blandy, D. C. Brown, G. McI. Forsyth, H. Fitzgibbon, P. J. Pugh, A. G. Buick, R. O. Holland, and C. R. Cone to be Temporary Surgeon Lieutenants.

ARMY

Colonel (Temporary Brigadier) M. J. Williamson, M.C., late R.A.M.C., has retired on retired pay and remains employed.

Colonel (Temporary Brigadier) A. D. Stirling, D.S.O., late R.A.M.C., has retired and remains employed.

Colonel W. A. Frost, O.B.E., late R.A.M.C., has retired on retired pay on account of ill-health.

Lieut.-Colonels (Temporary Colonels) S. D. Reid, from R.A.M.C., and E. A. Sutton, M.C., from R.A.M.C., to be Colonels.

Lieut.-Colonel E. Phillips, D.S.O., from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel S. P. Sykes has reverted to the rank of Major at his own request whilst employed during the present emergency.

Major and Brevet Lieut.-Colonel (Temporary Lieut.-Colonel) F. C. Tibbs to be Lieutenant-Colonel.

Major (Temporary Lieut.-Colonel) W. J. Robertson to be Lieutenant-Colonel.

Major J. E. Brooks to be Lieutenant-Colonel.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

The notification regarding Colonel L. E. H. Whitby, C.V.O., M.C., from T.A.R.O., in a *Supplement* to the *London Gazette* dated November 15, 1939, is cancelled.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Major N. W. Hammer to be Lieutenant, and temporarily relinquishes the rank of Major.

War Substantive Captains H. R. Lillie and A. G. Aitken have relinquished their commissions on account of ill-health.

War Substantive Captain D. C. Clark has relinquished his commission on account of ill-health, and is granted the rank of Captain. (Substituted for the notification in the *Supplement* to the *London Gazette* dated September 17, 1940.)

To be Lieutenants: J. R. M. Johnston, J. Cumming, D. M. Dunn, E. M. Glaser, K. Harris, A. R. Harrison, N. S. Kenchington, M. B. Longinotto, W. E. Macdougall, J. F. Macgregor, A. G. Porter, W. Recht, E. T. Renbourn, J. Ribeiro, H. M. Smallwood, W. Anderson, G. A. W. Angus, R. B. Boal, G. Boyd, V. A. Brady, T. J. Butler, B. Carr, S. Citron, C. L. Collins, H. Dallas, R. B. Davidson, W. Dickson, P. Duncan, K. B. Fraser, G. M. Gibb, K. J. Grant, R. H. V. Hafner, R. W. Harries, S. T. Hayward, A. Henderson, N. G. C. Hendry, J. P. Irwin, A. C. V. Jones, G. A. Jones, J. A. Jones, T. Kerrigan, J. B. Kyle, S. A. H. Lesser, G. P. McGowan, R. L. McMillan, I. M. Macgregor, R. M. Marshall, S. B. Mathews, W. E. Mathie, A. Milne, R. Murray, J. P. Singer, R. Taylor, C. Thomas, M. G. Valentine, R. L. Walsh, W. C. D. Walmsley, J. F. Webb, J. Weir, C. S. Whitehouse, A. F. Williams, D. G. Wright, D. E. Barton, J. Browne, A. R. Elsom, S. C. Gold, G. K. Harrison, G. H. Harvey, D. D. Howell, A. M. Hutton, J. H. Keesey, A. M.-M. Payne, F. A. Simmonds, K. Taraba, A. D. Willis, G. I. Harding, G. G. C. Taylor, W. A. Young, I. G. Anderson, P. S. G. I. Barclay, R. A. Bowen, L. Cherniack, J. R. Elwell, J. D. O. Fearnley, W. McC. Graves-Morris, J. U. Human, E. W. Jarratt, E. K. Kalmar, L. Rau, H. A. Shaw, R. H. Hodges, J. B. Arthur, P. H. Barkey, J. N. Blair, C. M. Boucher, J. H. F. Brotherston, N. L. Crabtree, R. Dalrymple, N. M. B. Dean, E. M. Foster, W. S. Gardner, P. Haden, J. Halliday, N. J. Hogan, F. Kane, D. Macartney, E. B. P. Madden, A. Marsh, R. Maxwell, J. C. S. Paterson, J. R. Platt, T. L. Price, M. P. G. Rawlinson, V. H. Roberts, J. H. B. Round, P. W. J. Searle, J. Sheehan, J. K. Steward, K. Teevan, W. J. Twohig, H. D. Venning, G. B. Walker, A. Waymouth, J. Webster, L. K. Wills, P. D. de Speville.

To be Medical Officers with the relative rank of Lieutenant: Dorothy B. Hudson, Elizabeth R. Cairns, Stella M. Coen, Margaret Emslie, Sheila M. Harper, Rebecca Billig, Margaret M. Shepherd, and Eva Dolan.

ROYAL AIR FORCE

AUXILIARY AIR FORCE

Flight Lieutenant A. L. Cowan has relinquished his commission on account of ill-health and retains his rank.

POST OFFICE MEDICAL OFFICERS' CAPITATION FEE

The General Post Office announces that, in view of the increase in private expenses, it has been decided to grant a further temporary increase of 6d. a year as from January 1 next, in the capitation fee payable to Post Office medical officers. The revised capitation fee will accordingly be 12s. a year from January 1, 1942.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following postgraduate courses in preparation for the January M.R.C.P. examination: (1) London Chest Hospital Course, 2 p.m. to 4 p.m., October 30 to December 2, alternate Tuesdays and Thursdays (one day weekly); (2) West End Hospital for Nervous Diseases hospital course, 2.30 p.m., Tuesdays and Fridays, November 25 to December 19; (3) it is hoped to arrange a course in general medicine, on Saturday afternoons for four weeks, starting about the middle of November.

A series of lectures on "War Surgery of the Chest" will be given at the British Postgraduate Medical School from Monday to Friday, October 27 to 31 (both days inclusive), beginning at 10 a.m. daily. The fee for the course is £1 1s. Officers of the armed Forces who wish to attend the lectures without payment of the fees should apply through their respective Director-Generals. Applications for admission should be addressed to the Dean of the British Postgraduate Medical School, Ducane Road, W. Further courses will be held as follows: November 10, War Surgery of the Nervous System; November 24, Operative Surgery in Wartime; December 15, War Surgery of the Extremities.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—Daily, 10 a.m. to 4 p.m., Medical Clinics and Operations and Paediatric Clinic, Dr. R. Lightwood; 11 a.m., Gynaecological Clinics, Mr. Green-Armytage. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical); 2 p.m., Lecture by Dr. T. H. Belt, The Pathology of Gastric Lesions. *Thurs.*, 2 p.m., Dermatological Clinic, Dr. R. T. Brain; 2 p.m., Radiological Demonstration, Dr. Duncan White. *Fri.*, 12.15 p.m., Clinico-pathological Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. V. B. Green-Armytage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—Royal Cancer Hospital, Fulham Road, S.W.: Daily, 10 a.m., Final F.R.C.S. Revision Course.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—At Tennent Institute, Church Street, Glasgow, *Wed.*, 8 p.m. Dr. J. N. Tennent: The Future of Ophthalmic Practice.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—*Mon.*, 2.30 p.m., Prof. A. J. E. Cave, Surgical Anatomy of the Nasal Fossa. *Tues.*, 2.30 p.m., Mr. R. Davies-Colley, Diseases of the Testicle. *Wed.*, 2.30 p.m., Prof. Cave, Surgical Anatomy of the Mouth and Jaws. *Thurs.*, 2.30 p.m., Mr. C. E. BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTH

HAMILTON.—On October 11, 1941, at Monk's Orchard, Beckenham, to Margaret Cecil (née Asbridge), wife of Dr. J. G. Hamilton, a son (Anthony John).

DEATH

DAVIDSON.—Suddenly, at The Kepties, Arbroath, on October 9, 1941, Fergus Macandrew Davidson, M.B., Ch.B.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 25, 1941

POLICY AND WORK OF THE BRITISH MEDICAL ASSOCIATION

The Executive Committee of the B.M.A., which, since the war began, has undertaken a great many of the duties that would have been carried out by the Council had more frequent meetings of that body been possible, met on October 14 under the chairmanship of Mr. H. S. SOUTTAR.

Industrial Medicine

An excellent piece of wartime work was laid before the Executive in the shape of the report of the Industrial Health Committee, appointed by the Council in 1940 to consider industrial medical practice in the light of the existing medical system and to discuss the possibilities of future development. This special committee, which was strongly representative of industrial medical practice, and also had observers from the Ministries of Labour and of Supply, has now produced a report running to forty-five foolscap pages, which the Executive Committee highly praised, authorizing its immediate publication, and its presentation by deputation to the Minister of Labour as soon as possible. A synopsis of the report and its recommendations will in due course be published in the *Journal*.

One member of the Executive said that he was disappointed that collieries had not been included within the committee's ambit. The committee's reference, however, was to the places covered by the Factory Act, and the committee was not constituted as it would have been if collieries were to be taken within its purview. The member who raised the point said that he would propose to the Council at its next meeting (on December 10) that a similar piece of work should be undertaken for collieries.

Resolutions from the Recent Conference

The various resolutions of the recent Conference of Representatives of Home Divisions were passed in review. Most of them were referred to the appropriate committees—the Insurance Acts, Hospitals, and Public Health Committees, and the Journal Board (those relating to certification, remuneration, and other matters had already been dealt with at a meeting of the General Practice Executive Committee on October 7).

A matter which was considered at length was the proposal for Discussion Groups to be organized within the Divisions. The idea was unanimously favoured, but it was felt that unless they were given "something to bite on" the result might well be diffuse and nebulous. The suggestion which found favour was that some of the problems now under consideration by the committees of the Medical Planning Commission might be set out in concrete form for discussion in the Divisions.

The method of issuing a periodical letter to all members of the Association, not to Divisional secretaries only, was favoured. Hitherto this has not been done because it was felt that members should look to the *Journal* for such information, but in wartime, with the restriction of the *Supplement*, it was thought that a letter written at intervals by the Secretary might be useful in maintaining interest in Association affairs.

On the resolution concerning the allowances paid to practitioners enrolled in the E.M.S. in coastal areas, the Secretary said that he had been advised that representations from practitioners in the coast towns were being forwarded. Another resolution urged that the Government be requested to provide adequate free medical attention for the dependants of those in the Forces. The Secretary said that representations to this effect had previously been made, and it was agreed that further representations be made at once to all three Departments concerned with the fighting Services and to the Ministry of Health.

The Advisory Role of the C.M.W.C.

One resolution from the Conference asked the Council to approach the appropriate authorities in order to make it clear that the Central Medical War Committee and the Local Committees are responsible for the allocation of medical personnel for recruitment for the armed Forces and for all branches of the E.M.S. and civil defence. It was felt that there was still some misunderstanding as to the role of the committees. The responsibility of the Central Medical War Committee and the Local Committees is advisory. In general, the Ministry does consult the Central Committee before making appointments, but the bodies are only expected to advise on allocation. It is obvious that the Government could not divest itself of its ultimate responsibility.

On the resolution which drew attention to what was described as "a dangerous extent of depletion" of the civilian medical profession and advocated part-time civilian practitioners for employment with isolated Service units, it was stated that the Central Medical War Committee had advocated the employment of part-time practitioners, and was doing all it could in that direction. As to "dangerous depletion," the view expressed by some members of the Executive was that while this might not be an entirely accurate description, such depletion was not far distant.

On the subject of petrol rationing, the Secretary read a letter he had received from the Petroleum Board setting out a scheme for an allowance of extra petrol in emergency cases. It was considered that although a certain delay in the supply of such petrol was apparently inevitable, this new arrangement, details of which are given elsewhere in this *Supplement*, would meet the difficulty in most cases.

The reply of the Ministry of Labour to the demand for the reservation of doctors' maidservants was also considered satisfactory. It promised that any representations which the employer might make would receive careful consideration before any woman registered under the Order was called for interview, that full account would be taken of the importance of her work and its actual nature, and, if it was decided that release should be made, every assistance would be given to the employer to find substitutes.

The final matter to engage the attention of the Executive was concerned with the Association's building, the south wing of which has suffered damage from enemy action. This damage will further delay the completion of the building operations when it is possible for these to be undertaken.

EMERGENCY PETROL FOR SUBSTITUTE CARS

The recent Conference of Representatives of Home Divisions of the B.M.A. discussed the difficulty in which a doctor who uses two cars for his professional work is liable to find himself when one of the cars breaks down and all the petrol coupons allocated to the other car have been used—a predicament which might well occur towards the end of a rationing period. The suggestion was made that the doctor might be permitted to use his supplementary allowance of petrol in either car, and the Council of the Association was asked to investigate this possibility.

Representations have been made to the Petroleum Department, and the following reply has been received:

"The solution suggested to you from within your Association would be very embarrassing to us, and might also land the practitioner himself in fresh difficulties. The Petroleum Board has been whole-heartedly and most effectively co-operating with us in a campaign to discourage dealers from supplying petrol against coupons in which any irregularity appears; and coupons marked in the special

way required under the scheme proposed to you would almost certainly be regarded as suspect and refused by dealers.

The following alternative proposal seems to me better both from your point of view and from *ours*. We should be prepared to issue a circular to D.P.O.s giving formal authority for what we know to be their practice in emergency cases, that when a medical practitioner whose car has broken down asks by telephone, telegram, or in person for an emergency ration for another car which he proposes to use as a substitute, the D.P.O. may grant immediately a small emergency supply of coupons bearing the number of the substitute car, on an assurance from the practitioner concerned that he has in his possession coupons for the broken-down car, at least equal to the emergency supply, and that he will return these as soon as possible with a written note of the circumstances.

The emergency practice to which I refer has not been confined by D.P.O.s to cases where the substitute car is the property of the applicant, and I do not propose to confine the formal authority to such cases: in other words, we should be prepared to make it applicable not only to those medical practitioners who have two cars of their own but to those who have only one and are compelled to borrow the substitute car from a colleague or a friend, provided in all cases that the emergency ration is sought only for a car used in substitution of one for which the applicant is receiving a supplementary ration and which has broken down."

The Department have been asked to issue the circular proposed in their communication, and it is hoped that this, although not an ideal solution, will go a long way towards meeting the difficulty.

CERTIFICATES FOR MILK FOR INVALIDS

The arrangements for the supply of fresh milk on a priority basis to certain classes of invalids have been revised in some important details since the statement published in the Supplement of October 4 (p. 73).

Lord Horder, as medical adviser to the Minister of Food, has sent a personal letter to each registered medical practitioner enclosing a confidential statement regarding the issue of medical certificates for the supply of milk on a priority basis under the Milk Supply Scheme. These two documents explain the reasons for the special arrangements and detail the conditions and procedure governing the issue of certificates for liquid milk to persons suffering from any of the prescribed medical conditions.

Under the arrangements as finally agreed, the medical practitioner will insert on the certificate the class number and letter of the medical condition by reference to the confidential statement referred to above. In this form the certificate will preserve in the fullest possible measure the confidential relation-

ship of patient and doctor. The certificate passes direct to the local Food Office, which issues the necessary documents to permit the supply and the purchase of the prescribed quantity of milk for the period authorized.

It is recognized that these arrangements impose upon members of the medical profession sole responsibility for the issue of medical certificates for milk in accordance with the Milk (Scheme of Supply) Order, which gives statutory authority to the arrangements and in accordance with the conditions prescribed by the Minister and circulated to doctors for their confidential use.

Correspondence

Extension of Health Insurance

SIR.—The *British Medical Journal* from time to time publishes letters from doctors criticizing approved societies, and it is unfortunate that some of the doctors who write letters do not always concern themselves with facts. In support of this statement may I draw attention to the letter signed "Observer" in your *Supplement* to the *British Medical Journal* of October 4, 1941. In referring to the extension of National Health Insurance to persons with an income limit of £420 he states: "No one so far seems to have grasped the real crux of the situation, which is a political and financial move by the approved societies to maintain their incomes." And he goes on to say: "This group, earning about £420 per annum, will certainly be made up of men above 45 years of age, whose incidence of disease is found to be high, consequently requiring considerable medical attention. This fact, combined with the loss of the young healthy men at present in the Army, warrants an increased capitation fee."

It may be that the inclusion of this group in National Health Insurance was a political move, but "Observer" is quite wrong in attributing it to the approved societies, and if he will refer to the newspapers and Hansard he will be able to satisfy himself on this point. Further, if "Observer" is right in thinking that the incidence of disease will be found to be high, requiring considerable medical attention, it is a little strange for him to state that the approved societies welcome these members in order to maintain their incomes, for he must know that the illnesses of such members requiring "considerable" medical attention as foreseen by him will result in the payment of "considerable" sickness benefit by the approved societies and the loss to them of "considerable" contributions on account of such sickness.

In fairness to approved societies I hope that when next "Observer" pleads for an increase in the capitation fee he will not couple it with an unwarranted attack upon approved societies.—I am, etc.,

Oct. 13.

"ANOTHER OBSERVER."

Mobile Surgeries for Bombed Areas

SIR.—The circular letter of September 30 from the Local Medical and Panel Committee for the County of London shows that a real attempt is being made to continue civilian medical services when surgery premises are rendered untenable by enemy action. The scheme of mutual assistance in loaning premises to unfortunate colleagues deserves the full support of all London practitioners.

It is, however, possible that circumstances may arise when alternative surgery accommodation is not available. A few "travelling surgeries" on the lines of the mobile first-aid vans would seem a practical solution in these conditions. No doubt such an innovation would cause criticism, but since the provision of medical services is of national importance sentiments should be disregarded.

If each practitioner in the London area contributed to a central fund, a small fleet of mobile surgeries could be made available to those members who were unable to find alternative premises immediately. The Government might be induced to contribute to this fund.—I am, etc.,

W. G. Kest, Oct. 7.

H. G. HOWITT.

Calling Up of Doctors' Maids

SIR.—Is it not time that the British Medical Association made serious representations to the Government about the need for domestic staff in the houses of medical men? I have been without a house-parlourmaid for over a fortnight, and was seriously considering the advisability of abandoning all attempt to continue practice without such necessary assistance; and I had spared no effort or expense to obtain one, but until to-day without avail. It is surely an undeniable contention that the house of a medical man cannot be maintained without domestic staff. A large proportion of the work done at my private house is essential Government work in connexion with the Forces. Some medical men will soon be compelled to give up practice because of the lack of candidates for domestic situations, and then it will be a serious matter for the Government and the people, and by that time an irremediable disaster. Certain Labour Party members stated in the House of Commons that we should be required to do our own domestic work, and we were to be levelled down to the same home conditions as those of "the working man." We can and shall be levelled down, but on that plane we cannot practise as specialists and had better obtain situations in armament factories; I have been on the verge of doing this.

This, like many other catastrophes of this war, will be realized too late, and something should be done now while there is still time.—I am, etc.,

Gloucester, Oct. 8

C. DE W. GIBB.

* This matter was the subject of a letter from the B.M.A. to the Ministry of Labour last July (*Supplement*, August 2, p. 18), and the Ministry's reply was published in the *Supplement* of September 27 (p. 70).—Ed., B.M.J.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Temporary Surgeon Lieutenants T. M. Wilson, C. Langmaid, W. A. Walker, G. W. Baker, A. E. S. Wood, P. Goodman, C. C. Gardner, W. R. Henderson, H. S. Hogg, J. D. Bradley-Watson, and P. T. Merlin to be Temporary Surgeon Lieutenants.

ARMY

Major-General A. D. Fraser, D.S.O., M.C., K.H.S., late R.A.M.C., and Major-General (Superannuated) R. C. Priest, C.B., K.H.P., late R.A.M.C., have retired on retired pay.

Colonel (Acting Major-General) C. M. Finny, O.B.E., K.H.S., late R.A.M.C., to be Major-General.

Colonel (Temporary Brigadier) G. Wilson, O.B.E., M.C., late R.A.M.C., to be Acting Major-General.

Colonel H. C. Winckworth, retired, late R.A.M.C., has reverted to the rank of Lieutenant-Colonel at his own request whilst employed during the present emergency.

Lieut.-Colonels F. D. Annesley, M.C., from R.A.M.C., and C. D. M. Buckley, M.C., from R.A.M.C., to be Colonels.

ROYAL ARMY MEDICAL CORPS

Major (Temporary Lieut.-Colonel) F. R. H. Mollan, M.C., to be Lieut.-Colonel.

Major G. O. F. Alley, M.C., to be Lieut.-Colonel.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Lieut. H. R. Findlay has relinquished his commission.

ROYAL AIR FORCE

ROYAL AIR FORCE VOLUNTEER RESERVE

To be Squadron Leader: C. A. E. I. Brownlee.

Flight Lieutenant H. Whittle has relinquished his commission on account of ill-health and retains his rank.

Flying Officers H. J. Lillie, C. W. R. Rayne-Davis, R. Robins-Browne, E. L. Ellis, J. Hoadley, F. E. Joles, F. R. Philips, B. A. Stoll, C. F. Wright, C. D. L. Lycett, C. S. Grossmark, R. H. Anthony, P. F. Barwood, F. Constable, P. J. Kelly, D. C. Bodenham, W. A. Steel, T. P. O'Brien, R. G. Blackledge, W. W. A. Gibson, and D. Boyars to be Flight Lieutenants (War Substantive).

Flying Officer R. W. Elliott has relinquished his commission on account of ill-health and retains his rank.

To be Flying Officers (Emergency): T. A. H. Monro, J. D. Anderson, J. A. Elliott, H. J. Fenn, S. Gibson, P. Haslam, A. A. Hill, K. W. B. Roston, and C. J. P. Seecombe.

To be Flying Officers: E. D. Arkell, J. F. Cartwright, J. P. Dodd, P. G. McE. G. Jones, W. T. S. McKean, C. J. K. Orr, and J. R. Hughes.

DENTAL BRANCH

T. G. Ward, L.R.C.S., L.R.C.P., to be Flying Officer (on probation).

INSURANCE ACTS COMMITTEE OF THE B.M.A.**Election of Direct Representatives for 1941-2**

The following direct representatives upon the Insurance Acts Committee have been *elected unopposed* for the groups mentioned:

- Group C.—Dr. H. F. Hollis (Leeds).
Dr. W. H. Smailes (Huddersfield).
Group F.—Dr. L. J. Picton (Holmes Chapel, Cheshire).
Group H.—Dr. E. Lewis Lilley (Leicester).
Group I.—Dr. J. A. Brown (Birmingham).
Group J.—Dr. D. J. B. Wilson (High Wycombe, Bucks).
Group L.—Dr. D. O. Twining (Salcombe, Devon).
Group O.—Dr. J. L. McKenzie Brown (Walthamstow).
Dr. C. F. T. Scott (Willesden).
Group P.—Dr. F. Gray (London, S.W.18).
Dr. E. A. Gregg (London, N.W.1).
Group Q.—Dr. S. E. A. Acheson (Belfast).

In the contested groups—namely, A, B, D, E, G, K, M, and N—the results were as follows:

- Group A.—Dr. W. Jope (Blantyre, Lanarks). *Elected*.
Dr. W. M. Knox (Glasgow). *Elected*.
Dr. A. F. Wilkie Millar (Edinburgh). *Elected*.
Dr. A. Simpson (Hawick, Roxburghs).
Dr. F. McEwen Sinclair (Glencairn, Fife).
Group B.—Dr. P. V. Anderson (Shildon, Co. Durham). *Elected*.
Dr. T. H. Bates (Newcastle-upon-Tyne).
Group D.—Dr. R. G. McGowan (Manchester). *Elected*.
Dr. F. M. Rose (Preston). *Elected*.
Dr. S. A. Winstanley (Urmston, Lancs). *Elected*.
Dr. A. Campbell (Accrington).
Dr. C. Baxter (Liverpool).
Dr. R. Cranna (Bolton).
Group E.—Dr. J. C. Davies (Wrexham). *Elected*.
Dr. W. E. Thomas (Ystrad-Rhondda). *Elected*.
Dr. C. M. Burrell (Aberystwyth).
Group G.—Dr. J. Hallam (Burslem, Stoke-on-Trent). *Elected*.
Dr. G. E. Elkington (Newport, Shropshire).
Group K.—Dr. J. C. Pearce (Diss, Norfolk). *Elected*.
Dr. C. M. Stevenson (Cambridge).
Group M.—Dr. T. MacCarthy (Sherborne, Dorset). *Elected*.
Dr. G. H. Barendt (Southampton).
Group N.—Dr. A. T. Rogers (Bromley, Kent). *Elected*.
Dr. W. G. Thwaites (Brighton). *Elected*.
Dr. S. A. Forbes (South Croydon).
Dr. N. E. Waterfield (Little Bookham, Surrey).

Scottish Subcommittee

The following direct representatives upon the Insurance Acts Scottish Subcommittee have been *elected unopposed* for the Groups mentioned:

- Group A.—Dr. I. M. MacLeod (Inverness).
Group B.—Dr. R. Bruce (Cults, Aberdeenshire).
Group C.—Dr. D. M. McGillivray (Dundee).
Group E.—Dr. J. M. Johnstone (Leven, Fife).
Group F.—Dr. A. F. Wilkie Millar (Edinburgh).
Group G.—Dr. D. Gunn (Loanhead, Midlothian).
Group H.—Dr. J. J. McMillan (Melrose, Roxburghs).
Group I.—Dr. I. D. Grant (Glasgow).
Dr. J. R. Langmuir (Glasgow).
Group J.—Dr. G. MacFeat (Douglas, Lanarks).
Group K.—Dr. W. A. Milne (Greenock).
Group L.—Dr. R. C. Hamilton (Hurlford, Ayrshire).
Group N.—Dr. W. J. Logie (Falkirk).

Nominations for Groups D and M have not been received; the vacancies will be filled by the Insurance Acts Committee.

G. C. ANDERSON,
Secretary.

B.M.A. : Meetings of Branches and Divisions**LANCASHIRE AND CHESHIRE BRANCH: LEIGH DIVISION**

At the annual meeting of the Leigh Division, held on October 12, the following officers were elected for 1941-2:

Chairman, Dr. S. H. Ryan. *Vice-Chairman*, Dr. A. Patton.
Honorary Secretary, Dr. J. H. Young.

The annual report adopted at the meeting stated that although activities of the Division had been necessarily curtailed owing to the war two meetings had been held during the year as well as two meetings to which all practitioners in the area of the Division were invited. Drs. A. McInnes, G. E. Hayward, and J. H. Young had been appointed medical officers to the Home Guard. The Protection of Practitioners Scheme had been extended so that a practitioner incapable of work owing to ill-health might receive benefit. Other subjects discussed during the year were private fees, the capitation fee, and medical certification. A suggestion, stated the report, that medical boards should be set up to examine persons desiring a change of occupation was rejected by the Ministry of Labour, Manchester.

B.M.A. : Branch and Division Meetings to be Held

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, October 30, at 2.30 p.m., Mr. L. R. Broster, "Some Biological Aspects of War"; 3.45 p.m., resuscitation demonstration by Dr. T. H. Boon and his clinic.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following postgraduate courses in preparation for the January M.R.C.P. examination: (1) general medicine, King Edward Memorial Hospital, Saturdays, 2 p.m. to 4 p.m., November 22 to December 13 (strictly limited to six postgraduates); (2) West End Hospital for Nervous Diseases course, Tuesdays and Fridays, 2.30 p.m., November 25 to December 19.

A military hospital medical society has arranged a week-end course in war medicine, to be held on Saturday and Sunday, October 25 and 26. On October 25, at 1.45 p.m., following an introductory address by the officer commanding, Colonel A. McKie Reid, there will be medical and surgical rounds, a discussion on eye injuries, and an x-ray examination. On October 26, at 9.30 a.m., plastic ear, nose, and throat surgery will be considered, there will be a skin demonstration, and a discussion on dyspepsia and gastroscopy. At 2.30 p.m. the programme includes resuscitation, oxygen therapy, anaesthesia in the field, and nutrition in war.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—Daily, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. Daily, 1.30 p.m., Post-mortem Demonstrations. Mon., War Surgery of the Chest series commences. Tues., 10 a.m., Paediatric Clinic, Dr. R. Lightwood. 11 a.m., Gynaecological Clinics, Mr. Green-Armytage. Wed., 11.30 a.m., Clinico-pathological Conference (Medical); 2 p.m., Lecture, Haemopoiesis and the Gastro-intestinal Tract (I), Dr. J. W. Clegg. Thurs., 2 p.m., Dermatological Clinic, Dr. R. T. Brain; 2 p.m., Radiological Demonstration, Dr. Duncan White. Fri., 12.15 p.m., Clinico-pathological Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. V. B. Green-Armytage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—London Chest Hospital, Victoria Park, E.: Thurs., 2 p.m., M.R.C.P. Course in Chest Diseases.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—At Tennent Institute, Church Street, Glasgow, Wed., 8 p.m. Dr. J. Pendleton White: The Oculist in the Law Courts.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Mon., 2.30 p.m., Prof. A. J. E. Cave, Surgical Anatomy of the Liver and Bile Ducts. Tues., 2.30 p.m., Mr. R. Davies-Colley, Tumours of the Intestines. Wed., 2.30 p.m., Prof. Cave, Surgical Anatomy of the Kidney and Ureter. Thurs., 2.30 p.m., Mr. C. E. Shattock, Tumours of Bone. Fri., 2.30 p.m., Prof. Cave, Surgical Anatomy of Certain Nerves.

ROYAL SOCIETY OF MEDICINE

Section of Odontology.—Mon., 2.30 p.m., Presidential Address by Mr. Harold Round: The Value of a Dental Department in a General Hospital.

Section of Physical Medicine.—Sat., Meeting at Bath. 12 noon, Demonstration of Cases and Clinical Material at the Royal National Hospital for Rheumatic Diseases; 1.15 p.m., lunch at Foorts Restaurant; 2.15 p.m., Demonstration of Hydrotherapy in the Royal Baths; 3 p.m., Discussion on the Value of Hydrotherapy in Rehabilitation; 4.30 p.m., tea in the Pump Room.

CHADWICK TRUST.—At Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., Tues., 2.30 p.m. Mr. J. C. Dawes (Ministry of Health): The Cleansing of Towns and Cities.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced: Stewarton (Ayrshire); Abercarn (Monmouthshire). Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by November 4.

MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT, 1925, for the County Court Districts of Downham Market, East Dereham, Fakenham, Holt, King's Lynn, North Walsham, Norwich, Swaffham, Thetford, and Wymondham (Circuit No. 32). Applications to the Under-Secretary of State, Home Office, Industrial Division, Room 37 (III), Cornwall House, Stamford Street, London, S.E.1, by November 4.

APPOINTMENTS

WATERS, H. S., M.B., F.R.C.S., F.R.C.O.G., Major, I.M.S., Professor of Midwifery and Gynaecology, Grant Medical College, Bombay.
WILSON, A. C., M.R.C.S., L.R.C.P., Consulting Psychotherapist to the State Criminal Lunatic Asylum, Broadmoor.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 1 1941

WAR NOTICE

National Register of Medical Personnel

It is of the utmost importance to the medical services of the country that the National Register of the profession maintained by the Central Medical War Committee should be kept up to date, and practitioners are asked, therefore, to help by notifying any change of address or of appointment. Up-to-date information regarding the following practitioners is requested for record purposes.

Name	Last Known Address
ALAN, Cuthbert Alastair	Walton Lodge, Pural, Harrogate.
BUNDSIDE, Grace	9, Marloes Road, W.S.
BULLOW, Harry	"Wayside," Guildford Road, Woking, Surrey.

YOUNG, Ruth Eleanor	23, Sunnyside, Mill Hill, N.W.7.

CENTRAL MEDICAL WAR COMMITTEE.
B.M.A. House, Tavistock Square, W.C.1.

Members of the Swansea Division of the B.M.A. and of the neighbouring South-West Wales Division recently heard Prof. J. A. Ryle speak in appreciation of a "very keen and competent generation at work in hospitals in air raids," and of their eagerness to share experience and to profit by the lessons of air attack. Prof. Ryle, who described himself as a "rather academic physician," was addressing a meeting, at which Dr. Kingston Knight presided, on "Lessons of the First Year's Air-raid Casualties." He had found that the usefulness of instructions issued centrally was limited: they could not be universally applied, because air-raid problems varied in different areas according to local geography, to the situation of hospitals in relation to the community, and to available personnel in casualty services and hospitals. There had, however, been tardiness in the exchange of experiences and useful information between one heavily raided area and another, and some of the provisions in the air-raid precaution services of places that had not suffered were still based on premises which experience had disproved. There was a lag between discovery and general application of new methods. In conclusion, Prof. Ryle said that of casualties admitted to hospital some 50% went to the operating theatre and 25% required resuscitation. About 10% required blood transfusion.

Correspondence

A. Medical Officer's Conscientious Objection

SIR,—I read with interest in the *Supplement* of to-day the correspondence relating to the action of the Dudley Council towards its M.O.H.

May I be permitted to say that I heartily approve of the action taken by the B.M.A., and it speaks well for the moral strength of the Association that it has acted in this manner. It proves its fairness and how judiciously it can act when circumstances demand it. It is not a question of bolstering pacifism, but an act of strengthening the position and view taken by the Government of the day, as you so well express it, in defending the liberty of action in accordance with expression of conscience relating to a member of the medical profession. I feel proud to say that I believe that this will strengthen the activity of the B.M.A. May I therefore tender my congratulations; I believe this firmness may be the means of bringing the Dudley Council to a realization of fair play and justice.—I am, etc.,

Cardiff, Oct. 18.

ARTHUR T. JONES.

SIR,—The County Borough Council of Dudley have suspended their medical officer of health on account of his conscientious objection to war. It is a strange instance of muddled thinking. There could hardly be stronger evidence of conscientiousness; and conscientious devotion to duty is a main requirement in a M.O.H. Is he suspended as a penalty for his action? Was it felt that an objector should be reduced at least to equal discomforts with those who serve? But Parliament in passing the Military Training Act determined that there should be no victimization of those who sincerely object to military service.

No, Sir, clearly the hearts of the Dudley councillors got the better of their heads. We may marvel, with them, at the mentality and moral courage of any man who can conceivably think it right to let others suffer untold hardship and die to bring him food, keep him in comfort, and prevent Nazidom from blotting out our civilization and reducing us to slavery, Prussian rule, and Nordic religion. But we are fighting for freedom, conscience included. We cannot go back on our word. The British public love a martyr. We may hope that the Dudley councillors may apply a wet towel to the head and reverse their decision.—I am, etc.,

House of Commons, Oct. 22.

FRANCIS FREMANTLE.

SIR,—The case for toleration is so well stated in the annotation on the subject of a medical officer's conscience that on the question of principle there can be nothing to add but grateful thanks for the stand the B.M.A. has taken.

But in this case the action of the local authority would seem to be not only wrong in principle but foolishly inappropriate, having regard to the procedure that has been set up for dealing with conscientious objectors. Registration as a conscientious objector is a first step, to be followed by interview by the tribunal. I know a case in which the objector was quite satisfied after this interview that his objection was in fact not a conscientious objection within the meaning of the Act. If the conscientious objection is upheld it is an excellent feature of the arrangements that the objector is given suitable work that will help the national effort. The councillors of Dudley, however, have no use for such finesse and do not hesitate to treat the whole of this carefully thought out procedure with contempt.—I am, etc.,

Oct. 21.

D.P.H.

SIR,—What about those doctors and councillors who have a conscientious objection to working with certain types of conscientious objectors? Let us save time and paper and get on with the war.—I am, etc.,

Wolverhampton, Oct. 20.

H. CAMPBELL ORR.

SIR,—As a member of the British Medical Association for over forty years, may I enter a protest against the action of the Association in refusing to insert the advertisement referred to in the *Supplement* of October 18 (p. 78). I submit that it is no part of the Association's functions to decide what are or are not the legal rights of a medical conscientious objector; that is surely a matter for the law courts. In the meantime this refusal to assist the borough council in getting a suitable medical officer might conceivably have grave consequences in the event of air raids or serious epidemics.

If Dr. McLennan has been suspended illegally he has a legal remedy. But while the legal issue remains undecided by an appropriate tribunal, the Association is, I think, not justified in trying to penalize the inhabitants of Dudley.

May I also suggest: (1) that Dr. McLennan had no need to register as a C.O., unless to escape service with the Forces; (2) that the quotation from Mr. Chamberlain's speech is irrelevant, as it deals with those "not prepared to undertake the ordinary combatant service"; (3) that a doctor serving with the Forces is not required to fight with or kill anybody: on the contrary he is given a unique opportunity to relieve suffering and save life among both friends and foes.—I am, etc.,

Manchester, Oct. 18.

J. STAVELEY DICK.

SIR,—Regarding the "spot of bother" between the Borough Council of Dudley and their M.O.H., is the B.M.A. wise in attempting a judgment at the present time? Surely the right procedure is for the doctor concerned to enter his protest and let it be judged by the tribunal which deals with objections by C.O.s. It is solely for this tribunal to decide in the first instance whether or not his reasons are sound. The argument in your leader based on a statement by the late Mr. Chamberlain can be counterbalanced by the fact that everyone who is not with us in this struggle is against us and therefore with Germany and all she stands for.—I am, etc.,

Tavistock, Oct. 20.

FRANK BRYAN.

* The Secretary of the B.M.A. states:

In regard to Dr. Staveley Dick's letter, the British Medical Association is not deciding a point "that is surely a matter for the law courts." Parliament has given the conscientious objector the right to register as such and to have his position considered by a tribunal established by law. Dr. McLennan has registered, and as no question of his recruitment has yet arisen his case has not yet been considered by a tribunal. Because he took a step which is his legal right—that of registering—he has been suspended from his office. His council has taken a step which, if not illegal, is contrary to the wishes of the Government as expressed by the late Prime Minister. The Association would not be justified in "trying to penalize the inhabitants of Dudley," but it is justified in trying to prevent the penalization of the inhabitants of Dudley and the victimization of its medical officer of health. In connexion with Dr. Staveley Dick's last paragraph, it should be pointed out that the War Office is unable to give assurance that an R.A.M.C. medical officer will not under any circumstances be required to assume combatant functions.

I agree with Dr. Bryan that the right procedure is to allow Dr. McLennan's case to be judged by the tribunal which deals with conscientious objection, and that "it is solely for this tribunal to decide in the first instance whether or not his reasons are sound." This is what the Dudley Council has not done. Following Dr. McLennan's registration, and without waiting for the consideration of his position by the tribunal established by law, the council has suspended him. The Association is not concerned with Dr. McLennan's conscience, and it is probable that the majority of its members will not agree with this point of view. But it must protest when a public body victimizes a medical officer because of his personal views and beliefs, religious or political, in spite of the fact that Parliament has established a tribunal for the consideration of such beliefs. In a war which is being fought to preserve freedom of belief the victimization by public authorities of medical officers on the ground of conscientious objection cannot be allowed to go unchallenged.

Halifax Division and a Circular Letter

SIR.—At a meeting of the Halifax Division of the B.M.A. held on October 12 the following resolution was passed:

"Whilst we do not condone the action of the Insurance Acts Committee in its negotiations with the Ministry of Health we disapprove the attempt of the Medical Practitioners' Union in a circular dated August 22, 1941, to capitalize the disaffection of members in the profession by asking them to withdraw their membership from the B.M.A."—I am, etc.,

L. GLICK.

Oct. 19.

Hon. Sec., Halifax Division of the B.M.A.

Capitation Fee and New Entrants to Insurance

SIR.—Like most of my colleagues I am very indignant at the acceptance of the new capitation fee of 9s. 9d. a year and the inclusion of a new class of insured personnel with salaries up to £420 a year. The argument used that this is the maximum the fund would allow is not convincing; obviously the answer is. If there is not enough in the fund to pay a living wage to the panel doctors the fund must be increased by additional levies on the insured and employers.

Another reason given was, I believe, that an increase in the capitation fee would set an example for increased salaries to higher-paid Civil Servants. If this is so we are entitled to pensions like the higher-paid Civil Servants; but when this was suggested to the Ministry of Health some years ago we were told we were not to be compared with Civil Servants, but were, in fact, contractors. Now which are we? We cannot be contractors when a pension is involved and Civil Servants when we ask for more pay; few contractors are expected to carry out their work at pre-war rates. Further, this attitude cannot be justified on the basis of payment in the 1914-18 war, or on the present cost-of-living figures as compared with the pre-1914 figures. As the new scheme includes a new class for which we are not under contract, I see no reason why we, as individual panel doctors, cannot refuse to accept the cards of these new entrants, and if everyone took up this attitude we might arouse some interest in the minds of those who are supposed to represent us.

Many labourers on my panel who earned under £3 a week in 1939 now get from £9 to £12 on work of national importance, but still they remain on the panel. How can this be justified, or how can the increase which they receive and which comes indirectly from the Exchequer be a part of the economy which allows no increase to panel doctors? I use the words "no increase" because I think the so-called increase of 9d. a head, in my own case at any rate, will prove to be a decrease when the loss of private fees due to the inclusion of the new class is taken into consideration. I should have thought that if a new class was considered for inclusion in N.H.I. the dependants of men in the Forces should have received the first preference. As it is the poor doctors have to attend many of them free because they cannot afford to pay. The B.M.A. has recently suggested that fees to private patients should be increased by 20% to cover increased practice costs: why are all increased practice costs charged to private patients and none to panel patients?—I am, etc.,

Natalie Peck, Oct. 19.

J. A. KENNETH DOUGLAS.

State Medical Service

SIR.—May I, quite unofficially, add a remark or two to your correspondence on a State Medical Service.

For almost the whole of my professional career I have been associated with a Government Department that provides free medical service, and has done so for nearly a century, for many thousands of its employees all over the country subject to a salary limit. This service is of a general medical practitioner type, and every effort is made to obtain the most suitable and conveniently placed medical officers. In most cases the majority of the staff entitled to free medical attendance avail themselves of these medical services. But it is not compulsory for them to do so, and they are at liberty, if they wish and are prepared to pay the fees, to attend any other doctor of their choice. Experience has shown that, however able and kindly an official

doctor may be, there is generally a minority who prefer, for personal or professional reasons, to attend some other doctor. But if every doctor were to be a State servant, to whom could these people turn?

Again—though I see no reason, given the right seniors, why medical officers in a State service should not have very considerable freedom and initiative in the treatment of patients—there are bound to be cases in which patients feel themselves to have been improperly or inadequately treated. In my own service all such patients have the right of appeal, either personally or through their unions or associations, and to furnish outside independent medical evidence on their behalf. But if every doctor were to be a State servant, to whom could such people turn?

Personally I feel that, whatever form of State Medical Service is adopted, there should be some "pool" of outside independent general practitioners and specialists from whom—both in the true interests of the public and the efficiency of the State Medical Service itself—salutary criticism could be forthcoming, and who would be capable of looking at the State Medical Service from outside. This would also provide an outlet for young men and women who wish to embrace medicine as a career but who may not wish—as an obligatory condition of becoming practising doctors at all—to be salaried State servants.—I am, etc.,

London, E.C., Oct. 17

H. H. BASHFORD.

This Certification Business

SIR.—In a mood of irritation, later changing to amusement, I made a list of certificates which I, a general practitioner, am expected to issue—most of which I have issued. It may be of interest to other members of the profession who do not have this responsibility.

Panel: First; intermediate; final; convalescent; voluntary 40F; monthly; sight-testing.

Public health and other authorities: Birth; death; stillbirth; disinfection; vaccination; infectious diseases, general; puerperal pyrexia; measles and whooping-cough; school, "unable" and "now able"; pensions, old age; pensions, Service, etc.; soldiers, grants of pay to wives and relatives; relieving officer, letters to.

Employers: Work, "unable, continues," and "unable, now able for."

Confinement: Reason for necessity to go to hospital or maternity home; maternity benefit.

Friendly societies: On; continuation: final.

Railway company: Rebate on season ticket on account of illness.

Hospital: Letters.

Connected with war: War injuries: Forms O. 1667; R.A.F. 1667; Navy S. 26. Masks, gas, special; fire prevention exemption; shelters, indoor; to enter prohibited areas; petrol for special reasons; workers, transfer from one area to another, and from one occupation to another. Food.—Milk, children and mothers; milk, extra, for invalids; eggs; glucose; olive oil, etc. Clothing.—Mothers, expectant; surgical belts, boots, etc.

Certificates of character.

—I am, etc.,

Oct. 19.

A. R.

Wartime Medical Certification

SIR.—In view of the attitude taken by the Ministry of Health in increasing the scope of National Health Insurance without the consent of the profession, I wish to draw attention to the very great increase in our work caused by the filling in of various Government forms—for example, milk forms, dependants' allowance forms, fire-watching exemption forms, certificates of the stage of pregnancy for extra wool rations, certificates recommending extra rations, etc. Have the Government Departments concerned obtained the consent of the B.M.A. before thus adding to our already grievous burdens, and has the question of payment for any of these services been considered?—I am, etc.,

Halesowen, Worcs, Oct. 15.

HERBERT W. BLAND.

* The Secretary of the B.M.A. states that the Association is at present in negotiation with the appropriate Government Departments on questions of wartime medical certification. Hitherto many certificates have been issued by Departments without consultation with the Association, but it is expected that this practice will now cease. A comprehensive statement on the whole subject will shortly be made by the Association.

N.H.I.: New Certificate Books

SIR.—Is it possible for you to publish the cost to the National Health Insurance of the recent change in certificate books?

When the organizing genius—a Civil Servant, I presume—has decided that such a change might still further curb the restless spirit of general practitioners, does he approach any representative body of medical men? If so, who concurred with the idea of scrapping a perfectly sound book containing, in one cover, first, intermediate, and final certificates, for three different ones? How many of the old books have been scrapped? Don't say it has been done to save paper, for we shall not believe that. We never were pestered by so many forms in the history of Britain.

Let the B.M.A. take the problem of certificates in hand and issue simple forms for every purpose with a definite charge to be made for each. Even then I suppose we shall occasionally meet the client to whom we refuse a certificate emerging from a neighbouring surgery with a form in his hand and his tongue scraped out. Forgive me if I seem bitter, but I have just been told that the cost of the change comes out of the pool which should have given us a "bob" instead of "ninepence." Is this the case?—I am, etc.,

Tarleton, Oct. 17.

L. CROFT.

** The Insurance Acts Committee of the B.M.A. was consulted in regard to the changes in the size and form of National Health Insurance medical certificates, as well as the proposal to eliminate the counterfoils. On being assured that the saving in paper would be substantial—some thirty tons per annum—the committee agreed to the changes as a wartime measure of economy. The saving in cost is not known, but it is certain that there will be no extra charge on N.H.I. funds.—ED., B.M.J.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

Acting Surgeon Lieut.-Commander B. W. Walford has been transferred to the Permanent List.

Surgeon Lieuts. F. P. Ellis, G. C. Denny, G. H. C. R. Critien, G. L. Hardman, L. R. Norsworthy, W. H. E. McKee, J. F. Meynell, R. M. Latta, W. Wilson, W. J. Latham, M. F. Sheehan, C. D. Coode, M. M. J. Enright, R. T. May, L. H. Duthie, and J. H. Mitchell have been transferred to the Permanent List.

ROYAL NAVAL VOLUNTEER RESERVE

Acting Surgeon Lieut.-Commander E. M. Buzzard to be Surgeon Lieutenant-Commander.

Probationary Temporary Surgeon Lieuts. G. A. Ballance, W. D. G. Troup, F. J. Brice, and D. Horton to be Temporary Surgeon Lieutenants.

ARMY

Colonel J. T. Simson, late R.A.M.C., having attained the age for retirement, has retired on retired pay, and remains employed.

Lieut.-Colonel (Temporary Colonel) J. C. A. Dowse, M.C., from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Major (Temporary Lieut.-Colonel) A. J. Beveridge, O.B.E., M.C., to be Lieutenant-Colonel.

Major J. M. Morrison has retired on retired pay on account of ill-health.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major J. Hare, O.B.E., has ceased to belong to the Reserve of Officers on account of ill-health, and has been granted the rank of Lieutenant-Colonel.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel C. Booth-Jones, T.D., having attained the age limit, has relinquished his commission and retains his rank.

Major J. F. Fraser, from supernumerary for service with O.T.C., to be Major. (Substituted for the notification in the *Supplement* to the *London Gazette* dated October 6, 1939.)

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

A. C. Dalzell to be Lieutenant without pay and allowances, and has been granted the unpaid acting rank of Major.

War Substantive Captain C. H. Atkinson, M.C., has relinquished his commission on account of ill-health, and has been granted the rank of Major.

Lieuts. E. B. Berry and J. C. Carson have relinquished their commissions on account of ill-health, and retain their rank.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following M.R.C.P. course in preparation for the January examination: Neurology, West End Hospital for Nervous Diseases, Tuesdays and Fridays, 2.30 p.m., November 25 to December 19.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetric and Gynaecological Clinics and Operations. *Daily*, demonstrations. *Tues.*, 10 a.m., Paediatric; 11 a.m., Gynaecological Clinic, Mr. C. L. 11.30 a.m., Clinico-pathological Conference. *Wed.*, 2 p.m., Lecture, Intestinal and Pancreatic Function and their Investigation, Dr. E. J. King. *Thurs.*, 2 p.m., Dermatological Clinic, Dr. R. T. Brain. *Fri.*, 12.15 p.m., Clinico-pathological Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. V. B. Green-Armytage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*London Chest Hospital*, Victoria Park, E.: *Tues.*, 2 p.m., M.R.C.P. Course in Chest Diseases.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—*Tues.*, 3.30 p.m. Ballot for election to the Fellowship.

Section of Surgery.—*Wed.*, 2.30 p.m. Discussion: Streptococcal Cross-infection in Wards. Openers, Prof. A. A. Miles, Prof. J. Paterson Ross, Dr. M. van den Ende, and Colonel L. Colebrook.

Section of History of Medicine.—*Wed.*, 3 p.m. Paper by Prof. A. T. Jurasz: The Foundation of the Polish Medical Faculty within the University of Edinburgh. Members of the Sections of Epidemiology and State Medicine, Medicine, Pathology, Surgery, and Therapeutics and Pharmacology are specially invited to attend the meeting.

Section of Otolaryngology.—*Fri.*, 10.30 a.m., Presidential Address by Mr. F. Watkyn-Thomas: Otitic Meningitis.

Section of Laryngology.—*Fri.*, 2.15 p.m. Presidential Address by Mr. E. D. D. Otolaryngologist in War. Surgeon Major D. Guthrie. Mr. V. E. Negi take part in the D. D. Dickson will

Section of Anaesthetics.—*Fri.*, 2.30 p.m. Presidential Address by Dr. A. D. Marston: The Centenary of Ether as an Anaesthetic.

APPOINTMENTS

EXAMINING FACTORY SURGEONS.—J. S. Bailey, M.R.C.S., L.R.C.P., for the Eye District (Suffolk); W. G. Brand, M.B., Ch.B., for the Adlington District (Lancashire); C. McDonald, M.B., Ch.B., for the Kilwinning District (Ayrshire); E. C. W. Maxwell, M.R.C.S., L.R.C.P., for the Robertsbridge District (Sussex).

LONDON COUNTY COUNCIL.—The following appointments in the Council's mental health services at the hospitals indicated in parentheses are announced. *Temporary Deputy Medical Superintendent*: Doreen P. Firmin, M.B., B.Ch., M.R.C.P., D.P.M. (Caterham). *Temporary First Assistant Medical Officer*: S. Le R. Switzer, M.R.C.S., L.R.C.P., D.P.M. (Tooting Bec).

B.M.A.: Branch and Division Meetings to be Held

KENT BRANCH: TUNBRIDGE WELLS DIVISION.—At Kent and Sussex Hospital, Tuesday, November 4, 8 p.m. Debate: "That in the opinion of this Meeting the Medical Profession would welcome the establishment of a State Medical Service." All medical practitioners and their wives are invited to attend.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, November 6, 2.30 p.m., Mr. G. F. Rowbotham: "Acute Head Injuries"; 3.45 p.m., surgical clinical demonstration by Mr. G. Y. Feggetter and his clinic.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTHS

JONES.—On October 14, at Highbury Nursing Home, Neath, to Audrey (née Turner), M.R.C.S., L.R.C.P., wife of Capt. J. Michael Jones, R.A.M.C., a daughter.

MONRO.—On October 19th, in Singapore, to Landon Carter (née Reed) and J. K. Monro, M.Ch., a daughter.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 8 1941

Correspondence

State Medical Service

Sir.—I have read your correspondence on Medical Planning and State Medical Service, and feel that medical practitioners, at this critical stage of the war, ought to organize themselves into a position to demand satisfactory conditions of service in the future, and not leave it entirely to the B.M.A. The Local Medical and Panel Committees would be a good rallying point. I am sure that those of us who have had a long experience of all types of practice favour a private contract between patient and doctor. The relation is frequently a very happy one, and the doctor usually receives more consideration than when under contract. Panel patients frequently take the doctor's services for granted, and the chronic patient is often overfastidiously on the doorstep, whereas the paying patient usually only comes when he feels it necessary. It is obvious that the Government has no intention of offering contract terms equal to private practice of pre-war days, and there is very little prospect of the pay in a whole-time service being any better than the inadequate panel-capitation fee.

In my view an improved N.H.I. service (without the Approved Societies) and administered by the profession would be more acceptable and produce better work than a whole-time service. It would enable those doctors who wish to undertake private practice to participate in both systems, instead of leaving the entire private field to osteopaths, herbalists, and the like! Practitioners should have beds and diagnostic facilities at their disposal in local hospitals and clinics, and be able to call in specialists when required. The capitation fee should not be less than £1, and, say, 1,500 patients should be the maximum for a doctor doing private work. This figure could be reduced if the practitioner was giving too much time to other professional work. Those who prefer contract practice could elect to do panel only, and could be allowed to accept more patients. A pension scheme should be instituted by deduction from the quarterly cheques and a contribution from the State. Better pay would enable the doctor to employ efficient secretarial help, so as to be more free for professional duties. Midwifery, child welfare, and other fields of work stolen by the Ministry of Health should be restored to those G.P.s able and willing to do the work in co-operation with specialists.

The majority of our able-bodied private patients, especially women, are being forced on to the panel by the Government and A.R.P. authorities. Many of them can still afford, and would prefer, to be private patients, but they become eligible for the panel because they are in receipt of a salary. There ought to be a total income limit for N.H.I. We all know that society will be linked to medical work in a greater degree after the war, whatever the economic system may be; but surely this can be achieved without whole-time State service, which, in my view, will be unjust to patient and doctor alike if introduced while capitalism and private enterprise continue in other walks of life.—I am, etc.,

LEWIS W. L. 14, Oct. 17.

C. WATNEY ROE.

Sir.—There were interesting letters in the *Supplement* of September 27, and I should like to take this opportunity of making some comments thereon. Dr. R. P. W. Shackleton thinks that vested interest in disease is all wrong, and I quite agree with him. The distinction between the Public Health Service and general practice is a purely artificial one, and the sooner some combination of both is brought about the better for all sections of the community. Most general practitioners

will, I think, agree that no small amount of their patients' ailments are due to a combination of bad housing and a faulty mode of living, yet the only remedy that a good many of us can offer is the traditional bottle of medicine with a certificate for a "week on the club." In other words, instead of dealing boldly with causes we are simply tinkering with effects.

Now Dr. J. M. McInnes makes the rather controversial statement that the N.H.I. Act has raised neither the reputation nor the professional standard of the general practitioner. Well, this may be his opinion, but it is certainly not that of most of my colleagues who were in practice in the pre-panel days. If Dr. McInnes could only hear their decidedly pungent views on the bad old days of pettifoggery "sick clubs" and "medical aid societies" he might be induced to modify his opinions. There is, I think, little doubt that the present-day insured person gets much better value for his money than did his father in the free-and-easy days of thirty years ago.

Then Dr. C. A. H. Franklyn, in connexion with his remarks about a State Medical Service, says that almost everyone would prefer to be treated as a private patient, but what worries them is how to pay their medical expenses. No doubt it does, because by the time most of them have paid their instalments on the house, furniture, car, radiogram, etc., there is not much left for the doctor, who is proverbially the first to be called and the last to be paid. Moreover, these people are quick to realize that if they do not keep up their payments as regards the items mentioned they will soon find themselves in the county court, whereas they know full well that the doctor will seldom, if ever, take such an extreme step. In other words, the doctor asks for it and invariably gets it!

And, finally, there is the letter of Dr. J. H. Moore, who thinks that there is such an appalling lack of unanimity, etc., in the profession. But, after all, is there anything so remarkable about this when one considers the diversity in type of general practice? Take, for instance, the much-debated subject of a State Medical Service. The average doctor in giving his opinion on this matter is bound to be influenced to a certain extent by the type of practice in which he is engaged. It would be, I think, safe to say that support for a National Service is definitely stronger in industrial areas than in rural ones. In semi-industrial districts and the smaller towns opinion would seem to be more or less evenly divided. It is also significant that the younger men are much keener on the idea than are their seniors; here, no doubt, again the personal equation is the deciding factor. There is, however, practical unanimity that the present N.H.I. scheme is unsatisfactory, the principal grounds of complaint being (1) the insufficient capitation rate and (2) the non-inclusion of dependants.—I am, etc.,

Leicester, Oct. 28.

E. J. O'SULLIVAN.

War Formulary for National Health Insurance Purposes

The attention of insurance practitioners is directed to the announcement in the *Journal* this week (p. 656) of the publication of the *National War Formulary*. A summary of its contents will be found on page 662. A copy of the *Formulary* is shortly to be issued free of charge to every doctor and chemist under contract with an Insurance Committee. It will be distributed through Insurance Committees, and will come into operation for National Health Insurance purposes on December 1 next.

Part VII of the Drug Tariff will be discontinued and Part III of the Tariff will be correlated to the *National War Formulary*. There will be a special issue of the Drug Tariff for December, and with it will be issued a list of the principal amendments necessitated by the new *Formulary*.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

Surgeon Lieut. N. M. McArthur to be Surgeon Lieutenant-Commander.

Surgeon Lieut. W. F. Viret (Emergency) to be Lieutenant-Commander (Emergency).

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Temporary Surgeon Lieuts. J. McClintock, F. S. Melville, G. A. Dingemans, G. S. Thomas, C. M. H. Rotman, W. R. D. Seymour, J. J. Foley, W. M. Douglas, B. R. Mitchell, and C. H. F. Wood to be Temporary Surgeon Lieutenants.

ARMY

Major-General R. C. Priest, C.B., K.H.P., has relinquished the appointment of Inspector of Medical Services.

ROYAL ARMY MEDICAL CORPS

The following Captains (Short Service Officers) have been appointed to permanent commissions: A. B. Dempsey, R. S. Hunt, G. B. Heugh, W. N. L. Haynes, and I. N. Fulton; (Acting Major) C. L. Lewis; (Temporary Majors) J. F. Wilson, W. Stewart, M.B.E., E. A. Smyth, J. R. Kellett, and K. G. F. Mackenzie; (War Substantive) Major (Temporary Lieut.-Colonel) J. A. Davidson.

War Substantive Captain F. R. How has relinquished his temporary commission on account of ill-health, retaining the rank of Captain.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

T. Tennent to be Lieutenant, without pay and allowances, and has been granted the unpaid acting rank of Lieutenant-Colonel.

D. J. O'Connell to be Lieutenant, without pay and allowances, and has been granted the unpaid acting rank of Major.

War Substantive Captain P. A. H. King has relinquished his commission on account of ill-health, and has been granted the rank of Major.

Lieuts. G. A. F. Quinell and D. I. C. Milton have relinquished their commissions on account of ill-health.

The notifications regarding Lieuts. J. C. R. Buchanan and R. C. Le Masle in *Supplements to the London Gazette* dated July 16, 1940, and August 26, 1941, respectively are cancelled.

To be Lieutenants: W. R. G. Atkins, C. J. R. Aubrey, C. W. G. Bryan, C. R. Ribband, A. Watt, R. Platt, J. Allan, W. J. Barclay, W. J. Hughes, J. L. Kirk, H. Acton, J. Beech, T. Y. Bennie, C. A. Birks, J. R. Boyd, C. S. Campbell, J. C. Coates, R. S. Dewar, G. M. Edington, S. C. Edwards, J. J. A. Embleton, E. M. Ensor, C. L. Ferguson, J. French, J. Gauld, M. B. H. Golden, M. H. K. Haggie, W. Hayes, J. F. K. Hutton, D. J. McI. Irvine, A. Jack, H. M. Jamison, A. K. Jones, N. U. Khan, W. Lamb, D. Lehan, N. S. Levantine, J. Livingstone, K. C. MacKelvie, A. McAllister, A. W. McBain, K. J. MacGinty, J. S. Main, G. E. Milne, N. C. Mond, D. G. Morris, A. P. Motley, H. A. Oatley, R. W. Orton, T. G. Owen, J. F. Perry, G. Platt, P. V. Pucci, I. Reubin, H. V. Sansom, G. Smith, W. C. Smith, D. C. Taylor, W. J. Taylor, A. P. Thomson, S. Tomback, W. S. Tulloch, P. Tytler, A. J. Walker, K. M. Wheeler, B. A. M. Williamson, C. H. Wood, J. Zigmund, W. Anderson, O.B.E., J. C. Hawks.

Dorothy M. J. Emslie has been granted an emergency appointment as medical officer, with the relative rank of Lieutenant. (Substituted for the notification in a *Supplement to the London Gazette* dated October 7, 1941.)

SOUTH AFRICAN MEDICAL CORPS

Lieut. H. J. Knight, 1st Rhodesia Motorized Field Ambulance, to be Temporary Captain.

ROYAL AIR FORCE

ROYAL AIR FORCE VOLUNTEER RESERVE

G. A. Smart to be Flight Lieutenant (Emergency).
Flying Officers R. S. Carpenter, J. D. Craig, R. W. K. Purser, R. G. Robinson, B. Roditi, J. L. Lawrence, G. A. Mandow, J. W. Pooley, A. Russell, M. I. Cookson, G. Cormack, T. P. Hopkins, F. W. T. Davies, G. M. Jones, D. Macpherson, A. D. Messent, S. Rosehill, J. M. Smiles, J. C. A. L. Colenbrander, P. P. Brown, W. L. James, I. G. Lennox, D. C. Russell, J. Spears, J. H. Ward, D. W. Boatman, L. Nancekivell, D. P. O'Sullivan, J. Colover, A. G. Edwards, L. C. Liddell, and R. G. Crawford to be Flight Lieutenants (War Substantive).

To be Flying Officers (Emergency): P. H. Bell, H. Avery, F. T. P. Bergin, D. Cowan, H. V. W. Elwell, R. C. Fraser, Q. St. L. Myles, J. R. Slessor, A. Standeyan, J. M. Wilkin, I. G. Williams, J. L. Boyd, T. I. Gordon, W. D. Smith, P. W. G. Sutton, N. J. Burnand, G. H. Flack, A. T. Hawthorne, D. L. Henderson, E. H. B. Hopkins, R. W. McDowell, and H. Zinobor.

DENTAL BRANCH

A. G. Beaton, M.R.C.S., L.R.C.P., to be Flying Officer (Emergency).

B.M.A.: Branch and Division Meetings to be Held

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, November 13, 2.30 p.m., Dr. J. C. Spence: "National Food Policy in Wartime"; 3.45 p.m., medical clinical demonstration by Dr. A. G. Ogilvie and his clinic.

B.M.A.: Meetings of Branches and Divisions

SHROPSHIRE AND MID-WALES BRANCH

At the annual general meeting of the Shropshire and Mid-Wales Branch, held at Shrewsbury on October 14, with Dr. C. U. Whitney in the chair, the following officers were elected for the ensuing year:

President, Dr. J. Aubrey Ireland. *Vice-President*, Dr. Whitney. *Chairman of Clinical and Pathological Section*, Dr. R. N. Urwick. *Honorary Secretary*, Dr. D. A. Urquhart. *Representative in Representative Body*, Dr. G. Elkington.

A tribute was paid to Dr. George Mackie for long service faithfully rendered as the representative of the Branch at Annual Representative Meetings of the Association. Dr. Ireland delivered his presidential address on "The Work of a Medical Board," which was much appreciated and for which he was heartily thanked.

POSTGRADUATE NEWS

The Fellowship of Medicine announces an M.R.C.P. Course in Neurology to take place at the West End Hospital for Nervous Diseases, on Tuesdays and Fridays, at 3 p.m., from November 23 to December 19.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetric and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m., Post-mortem Demonstrations. *Mon.*, Course on War Surgery of Nervous System commences. *Tues.*, 10 a.m., Paediatric Clinic, Dr. R. Lightwood; 11 a.m., Gynaecological Clinic, Mr. V. B. Green-Armytage. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical); 2 p.m., Lecture, Pathology of the Intestinal Tract (I), by Prof. J. H. Dible. *Thurs.*, 2 p.m., Dermatological Clinic, Dr. R. T. Brain. *Fri.*, 12.15 p.m., Clinico-pathological Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. V. B. Green-Armytage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1 Wimpole Street, W.—*London Chest Hospital*, Victoria Park, E., *Thurs.*, 2 p.m., M.R.C.P. Course in Chest Diseases.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Sections of Therapeutics and Pharmacology, and Medicine.—*Tues.*, 2.30 p.m. Discussion: The Kidney and Hypertension. Openers, Prof. Arthur Ellis, Dr. Clifford Wilson, Prof. G. W. Pickering, and Dr. Robert Platt. Followed by Dr. Geoffrey Evans and others. *Clinical Section.*—*Fri.*, 2.15 p.m. Meeting at St. Mary's Hospital, W. *Section of Ophthalmology.*—*Fri.*, 3.30 p.m. Paper by Dr. A. J. Ballantyne: Angiomatosis of the Retina: Account of a Case, including the Histological Result of X-ray Treatment. *Section of Neurology.*—*Sat.*, 10.30 a.m. Clinical and pathological meeting at Chase Farm Hospital, The Ridgeway, Enfield.

CHADWICK TRUST.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., *Tues.*, 2.30 p.m., Mr. F. R. Hiorns: Hygiene Technique in Building, or the Economic, Psychological and Health Aspects of Surface Treatment.

PADDINGTON MEDICAL SOCIETY.—At St. Mary's Hospital, W., *Tues.*, 3.45 p.m. Debate: How to Solve the Night Call Problem in London.

APPOINTMENTS

BOND, K. E., M.B., B.Chir., F.R.C.S., Temporary Surgeon to Outpatients, Hampstead General and North-West London Hospital.

MORLEY, H. S., M.D., M.R.C.P., Examining Factory Surgeon for the Midhurst District (Sussex).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTH

MORTON.—On October 9, to Florence J. R. Beattie, D.Sc., wife of Captain W. R. M. Morton, R.A.M.C., a son.

ENGAGEMENT

MATTISON—DUNCAN.—The engagement is announced between Flying Officer Leslie H. Mattison, M.R.C.S., L.R.C.P., D.P.H., elder son of Mr. and Mrs. Ellis Mattison of Manchester, and Miss Sheila Duncan, elder daughter of Mr. and Mrs. D. K. Duncan of Hendon, residing at "Avoncliffe," Alveston, Stratford-on-Avon.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 15 1941

ECONOMY IN DRUGS IN WARTIME SUPPLEMENTARY LIST BY THE THERAPEUTIC REQUIREMENTS COMMITTEE

Earlier this year the Therapeutic Requirements Committee of the Medical Research Council issued a memorandum on Economy in the Use of Drugs in Wartime,* which was published in these columns on March 22 (p. 33). The committee has now issued a first supplement to that memorandum, which we print below.

[As before, to facilitate reference the drugs have been grouped in their respective categories.]

* Indicates that the classification has been changed.

A. Drugs which are at Present either Regarded as Essential or are Readily Available

Drug	Substitute or Equivalent and Remarks
Amethocaine	
Diphenan	
Hexazole	
Metaphothone	Synthetic Vitamin K, 2-methyl-1:4-naphthoquinone
Mesulphen	
Oleum Cocos	
Orthocaine	
Phenacynium-Solubile	Sodium Diphenylhydantoinate
Picodrine	
Picran	
Picparv	
Pictharum	
Sifrol	
Sera and Vaccines, Veterinary (listed separately as 32 items, but not included here)	

B. Drugs which are Essential for Certain Purposes but not for Others, and in the Use of which Strict Economy should be Observed

Drug	Substitute or Equivalent and Remarks
*Acidum Acetylsalicylicum	Strict economy is essential. Phenol (q.v.) is the raw material
*Acidum Phosphoricum	
*Acidum Salicylicum	Strict economy is essential. Phenol (q.v.) is the raw material
*Coccus Gonadotrophic Hormone from pregnant mare's serum	
Gonadotrophic Hormone from pregnancy urine	
*Hamameli	
*Lebelia	
*Prenol	Required for the manufacture of munitions. Strict economy is essential. Substitutes: Chlorocresol, chloroxylenol
Progesterone	
*Sodi Phosphas	
*Sodi Phosphas Acidus	
*Sodi Salicylas	Strict economy is essential. Phenol (q.v.) is the raw material
*Sulphacetamide	This drug is in short supply
*Sulphadiazine	Supplies are strictly limited
Sulphaguanidine	Supplies are strictly limited and should be reserved for the treatment of intestinal infections
*Sulphathiazole	Supplies are strictly limited and should be reserved chiefly for the treatment of staphylococcal infections

C. Drugs which are not Essential and do not justify Importation or Manufacture for Home Use in Wartime

Drug	Substitute or Equivalent and Remarks
Acidum Hypophosphorosum and its salts	
Celery Seed	
Cummin	
Euphorbia	
Extractum Hepatis Liquidum	
Extractum Hepatis Siccum	
Galangal	
Grindelia	
Kola nuts	
Leptandra (Black root)	
Mandrake	<i>Mandragora autumnalis</i>
Pennyroyal	
Prunus Serotina	
Quince Seeds	
Raspberry Leaves	
Rubiazol	Substitute: Sulphanilamide
Sarsaparilla	
Sassafras	
Serpentary	
Skullcap	
Slippery Elm Bark	

The liver extracts are now controlled under a Defence Regulation, the Liver Extract (Regulation of Use) Order, 1941, which states that: (1) liver extracts shall not be administered otherwise than to persons suffering from pernicious anaemia or other megalocytic anaemia; (2) liver extracts so administered shall not be administered otherwise than by means of injection. If a remedy for oral administration in pernicious anaemia is required, a preparation of hog's stomach should be used.

List of Equivalents

Acaprin	Pirevan and Piroparv are identical
Albucid	Diphenan is identical
Butolan	Diphenan is identical
Cignolin	Dithranol is identical
Decicaine	Amethocaine is identical
Liver	See Extractum Hepatis Liquidum
Mitigal	Mesulphen is identical
Orthoform	Orthocaine is identical

Notes on Prescribing

Liquid Paraffin.—There is a serious shortage which is not likely to be relieved under present conditions.

Glycerin.—The use in medicine is now limited to the manufacture of preparations of the B.P. and B.P.C., and to the dispensing of prescriptions used by medical practitioners.

Sulphonamides.—Sulphanilamide is the most economical drug for general use. Sulphadiazine, sulphaguanidine, sulphapyridine, and sulphathiazole should be prescribed only when there are special indications.

Early this year local authorities were asked by the Ministry of Health to supply simple four-weekly totals of new notifications of tuberculosis (*Journal*, February 8, p. 207). The Ministry now asks in Circular 2498 that special steps should be taken to ensure that the returns reach the Department not later than six days after the end of the four-weekly period to which the return relates. Considerable importance is attached to these statistics, and failure to furnish returns immediately after the end of each four-weekly period appreciably reduces their value.

Correspondence

A Medical Officer's Conscientious Objection

SIR,—I cannot believe that the attitude of the B.M.A. towards the Dudley County Borough Council will, as you state in your annotation (October 18, p. 553), "no doubt be endorsed by the medical profession generally." The M.O.H. of a county borough has important and responsible duties in the war effort in connexion with the E.M.S. and A.R.P. organizations, and these duties in the case of air raids or invasion might differ little, if at all, from those of a senior R.A.M.C. officer under active service conditions. If a M.O.H. has conscientious objections to serving "with the armed Forces," what is to be his attitude in the event of hostilities, aerial or otherwise, in the vicinity of his own town, when, presumably, defensive measures by armed Forces would be in progress? Would he cease to direct his organization because he would have to act in conjunction with the armed Forces? In this war the people of Britain are united in one great effort, and they cannot allow anyone to hold a responsible position in which he might conceivably be driven by his conscience to detract, however little, directly or indirectly from that effort.

Your refusal to insert an advertisement for a temporary successor in what you recognize as a key post is, I think, merely obstructive.—I am, etc.,

The University, Sheffield, Oct. 20.

G. A. CLARK, M.D.

SIR,—In your description of the action the British Medical Association has taken over the case of Dr. McLennan you proclaim your confidence that this action will be endorsed by the profession generally. I believe that confidence to be misplaced. A considerable section of the profession, of whom I am one, most emphatically do not endorse it; in fact we deplore it.

The spectacle of Dr. McLennan "looking deeply into his conscience" and making the difficult decision to continue in the job he obviously prefers deserves closer examination. To what exactly does Dr. McLennan's conscience object? The accepted basis of conscientious objection is surely an inability to justify the taking of human life. What, then, is the doctor's case? No one is asking him to kill under any circumstances. If his objection is that service in the armed Forces sustains the war effort, how can he reconcile service in any other Government Department? You yourself appreciate his value in this respect when you mention the shortage of civilian doctors.

On analysis it would seem that you are protesting against the logical answer to Dr. McLennan's action. If he cannot bear to co-operate in the national war effort he has obviously no place in the service of a Government entrusted with the prosecution of the war. The County Borough Council of Dudley have simply recognized this fact and acted upon it. It is their decision which deserves endorsement, a more difficult and invidious one under the circumstances even than Dr. McLennan's.—I am, etc.,

Waterbeach, Cambridge, Oct. 28.

D. STAFFORD CLARK.

SIR,—I am contented to leave other points dealt with in my letter (*Supplement*, November 1, p. 86) to the judgment of my colleagues. I think, however, it would be of general interest to learn whether all medical officers in the Forces now receive training to fit them for "combatant functions." I have good reason for believing that in 1914-18 some medical officers received no such training; whether others had that advantage I do not know.—I am, etc.,

Manchester, Nov. 1.

J. STAVELEY DICK.

SIR,—Regarding the controversy at Dudley, however much individual opinions may differ it is the duty and privilege of the B.M.A. to support its members against local bodies when that action is contrary to the law of the land, as in this case. The same position sometimes arose in the early days of national

health insurance when local Insurance Committees tried to override central regulations. The B.M.A. is to be congratulated on the courageous action it has taken.—I am, etc.,

Bath, Oct. 30.

CHARLES A. MARSH.

SIR,—We wish to say how entirely we approve of the line the B.M.A. have taken in the matter of the Dudley M.O.H. and of the example that they have set to the country in its general vindictive attitude towards conscientious objectors. We know they will be inundated with criticisms from the belligerent patriots, so we wish to show appreciative encouragement from some of the more broad-minded.—We are, etc.,

MADELINE MALCOLMSON.

Hereford, Oct. 25.

E. W. MALCOLMSON.

SIR,—May I congratulate the B.M.A. in their criticism of the action of the Dudley Borough Council in dismissing its medical officer of health for his conscientious objection? I am sure no one would be foolish enough to construe their action as that of an Association whose members' views all agree with those of the doctor concerned. All the more credit is due in that they can recognize and support the liberty of conscience of their members.—I am, etc.,

Anglesey, Oct. 31.

F. CHARLOTTE NASH.

"Present Discontents"

SIR,—In the days of our innocence when we guilelessly pondered on the status of the "Beloved Physician" our opiate was duly administered by tutors out of touch with workaday medicine. In moments of semi-wakefulness we may have noted that though sophisticated hypocrites referred to members of the nursing services as "ministering angels," these same "angels" were being mercilessly worked to death. When we each in turn took our spade to make a job well done we looked in vain for "the honour and the glory." Our first "locums" oft revealed genteel poverty and sometimes worse.

We have our politicians, our senile celebrities, and most unfortunately a superabundance of "Peter Pans" who are still babbling in schoolboy and tutorial fashion; delivering up our professional brethren, to be imposed upon at every turn; and acquiescing in the steady destruction of our status. It is evident that there is "something rotten in the state of Denmark." In this our Parliament we are still treated as schoolboys; not to be trusted with the bigger things of life, but to be presented with plans already cut and dried, and without adequate opportunity for discussion or expression of opinions; regimented by autocratic officials who assume the role of self-appointed arbiters within the professional fold.

What is the remedy for our present discontents? Is it possible to infuse habits of mind and action, more in keeping with democratic ideals, into the workings of our Association? Can we remove the entrenched "dichards" and the "Peter Pans" without destroying the worthwhile edifice, and in time to save us from degradation into slavery?

In its present public form our *Journal* cannot be regarded as providing a free and natural forum for the exchange of views between professional colleagues. The *Supplement* should be published as a separate "News Letter" entirely apart from the *Journal* and for private circulation to the medical profession only. It should serve for free exchange of news, views, and ideas, with freedom to criticize adversely; and no censorship, official or otherwise. This is a real necessity in these difficult days, with restricted travel and small opportunity for personal contacts. We must be told the facts, freely, fully, and without restraint; left to decide on our own paths as free men; not presented at each turn with a *fait accompli* emanating from a secret conclave. Reforms are long overdue, and must come now! It will not suffice to say "the times are out of joint."—I am, etc.,

Birmingham and Midland Eye Hospital, Oct. 28. M. TREE, F.R.C.S.

District Medical Officers' Duties

SIR,—Has the B.M.A. noted the feeling of district medical officers caused by the very large numbers of holders of supplementary pensions being placed in the position of having free medical attendance, many in the past having paid their doctors

all fees, and a number were paying quarterly contributions local medical services? How is it that these extra duties, about any extra salary and indeed with loss of private fees of public medical service, have been put on to the district medical officers all over the country? These extra duties are only now being realized by the district medical officers as pension officers go round telling the pensioners that they are entitled to free medical attendance and how to obtain it. Under paragraph 7 of Circular 2105 Ministry of Health strict nurses are recommended for extra payment. Why not district medical officers?—I am, etc.,

SIDNEY MATTHEWS.

22nd Nov. 1941, Oct. 23.

B.M.A.: Diary of Central Meetings

DECEMBER

Wed. Council, 10 a.m.

B.M.A.: Branch and Division Meetings to be Held

ABERDEEN BRANCH: CITY OF ABERDEEN DIVISION.—At Royal Infirmary, Foresterhill, Aberdeen, Thursday, November 20, 8.30 p.m. M.A. Lecture, Dr. A. F. Wilkie Millar: Medical Planning—Present Provisions, the Problem, General Principles. Members of Aberdeen and Kincardine Counties Division and non-members of the Association are invited to attend.

BATH, BRISTOL, AND SOMERSET BRANCH: BRISTOL DIVISION.—At Bristol University, Thursday, November 20, 3 p.m. Prof. J. A. Wood: "The Treatment of Gas Casualties." 5.30 p.m. meeting of "The Galenicals." Drs. I. G. Davies and K. E. Cooper: "Tracking Down an Epidemic." All medical practitioners will be welcome at both meetings.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, November 20, 2.30 p.m., Address to be arranged later. 3.45 p.m., clinical demonstration of oral pathology at Newcastle-upon-Tyne Dental Hospital by Prof. R. V. Bradlaw.

NORTHERN IRELAND BRANCH.—At Whitla Medical Institute, Thursday, November 20, 12 noon. Presidential address by Dr. F. P. Montgomery: "The Future of the Hospitals."

B.M.A. LIBRARY

The following books were added to the Library during August and September:

- Amor, A. J.: *An X-ray Atlas of Silicosis*. With translations into French by R. E. Horne. 1941.
- Bassford, F.: *Poisons, their Isolation and Identification*. 1940.
- Bassett, J. Y.: *The Medical Reports of John Y. Bassett, the Alabama Student*. 1941.
- Blond, K.: *Haemorrhoids and the Treatment*. 1940.
- Bowley, J.: *Personality and Mental Illness: An Essay in Psychiatric Diagnosis*. 1940.
- Brinkus, P. J.: *Your Teeth: Their Past, Present, and Probable Future*. 1941.
- Burgess, P.: *Who Walk Alone: The Life of a Leper*. 1941.
- Cernock, G. C. (editor): *Hospitals under Fire: But the Lamp Still Burns*. 1941.
- Darling, H. C. Rutherford: *Surgical Nursing and After-treatment*. Seventh edition. 1941.
- Edley, W. H., and Daldorf, G.: *The Avitaminoses: The Chemical, Clinical, and Pathological Aspects of the Vitamin Deficiency Diseases*. Second edition. 1941.
- Finlay, C. E.: *Carlos Finlay and Yellow Fever*. Edited by M. C. Kahn. 1940.
- Franchiger, E., and Hofmann, W.: *Die Nervenkrankheiten des Kindes*. 1941.
- Heater, E. E.: *Textbook of Histology for Medical Students*. Second edition. 1941.
- Holmes, W. H.: *Bacillary and Rickettsial Infections, Acute and Chronic*. 1940.
- Hurst, A. F.: *Medical Diseases of War*. With the co-operation of H. W. Barber, H. B. F. Dixon, et al. Second edition. 1941.
- Kovacs, R.: *Physical Therapy for Nurses*. Second edition. 1940.
- Kruse, F. H.: *Physical Medicine: The Employment of Physical Agents for Diagnosis and Therapy*. 1941.
- Lambert, D.: *The Medico-Legal Post-Mortem in India*. Second edition. 1941.

- Zoethout, W. D., and Tuttle, W. W.: *Textbook of Physiology*. Seventh edition. 1940.

B.M.A.: Meetings of Branches and Divisions

CEYLON BRANCH

The Ceylon Branch celebrated its fifty-fourth anniversary by holding sectional meetings on July 22, 23, 24, and 25. The president, Dr. G. COOKE, occupied the chair at the opening proceedings on July 22 and addressed the meeting. The Section of Medicine then met under the chairmanship of Dr. P. C. C. DE SILVA. Dr. E. M. WULRAMA read a paper on "Pneumonia" and gave statistics of cases in all the Ceylon hospitals before and after treatment with sulphapyridine. Drs. J. R. BLAZE, V. GABRILL, G. A. W. WICKREMESINGHE, V. E. P. SENEWIRATNE, P. R. THIAGARAJAH, G. COOKE, G. S. SINATAMBY, S. R. GUNWARDENE, S. L. NAVARATNAM, MAY RATNAYAKE, and P. C. C. DE SILVA took part in the subsequent discussion. On July 23 the Section of Obstetrics met, with Dr. MAY RATNAYAKE in the chair. Dr. RICHARD CAMBERA read a paper on "The Occipito-posterior Position" and Dr. G. A. W. WICKREMESINGHE, P. DE S. WULSEKERE, S. L. NAVARATNAM, P. R. THIAGARAJAH, G. COOKE, and the CHAIRMAN took part in the discussion which followed. The Section of Surgery met on July 4, Dr. J. H. F. JAYESURIYA presiding, when papers were read by Dr. G. S. SINATAMBY on "Modern Methods in the Diagnosis and Treatment of Syphilis"; by Dr. MAY RATNAYAKE on "Venereal Diseases in Women"; and by Dr. D. P. BILLIMORIA on "The Ophthalmic Aspect of Venereal Diseases." Drs. A. S. RAJASINGHAM, P. B. FERNANDO, W. G. WICKREMESINGHE, and P. C. C. DE SILVA contributed to the general discussion. On July 25 the Section of Public Health met under the chairmanship of Dr. W. G. WICKREMESINGHE. Papers on "Venereal Diseases" were read by Dr. M. J. A. SANDARANGERA (the public health aspect) and Dr. P. B. FERNANDO (the physician's point of view). Dr. C. J. L. MISSE gave a summary of the routine treatment given at the out-patient department of the Colombo General Hospital. Drs. C. D. AMERESINGHE, G. COOKE, S. L. NAVARATNAM, G. A. W. WICKREMESINGHE, D. DE SILVA, and W. M. DE SILVA took part in the subsequent discussion.

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION

At a special meeting of the Bournemouth Division, held at the Royal Victoria and West Hants Hospital, Boscombe, on October 1, with Dr. C. A. BASKER in the chair, Dr. D. M. BIGBY (Southampton) gave an address on "The Clinical Aspect of Air-raid Casualty Work."

Dr. Bigby, confining his remarks to air-raid casualty work up to the time of the patient's admission to hospital, first described the organization in his area. He referred to work at the site of the incident, at the clearing zone, and at the evacuation zone, and then dealt with the co-ordination of various services, including the duties of wardens, police, rescue parties, and first-aid parties. He stressed the importance of rescue parties, inasmuch as 30 to 40% of the casualties were trapped, and he described how one man had been buried for fifty-three hours and yet had been rescued alive. The mobile first-aid posts, he said, had been amply justified. The maximum number of casualties passing through any one fixed post in any one raid had been seventy-six, and they had plenty of emergency casualty beds in the town. In his opinion, in spite of some little delay in treatment, all casualties should go to first-aid posts before being admitted to hospital; the condition of patients was much better where they had been transported in an ambulance rather than in lorries or any other type of vehicle. Dr. Bigby then circulated an analysis of about 1,000 casualties treated at first-aid posts, describing the various types and the site of the injuries.

After the address questions were asked by members, and a hearty vote of thanks was accorded to Dr. Bigby for the interesting and valuable talk he had given.

KENYA BRANCH: MOMBASA DIVISION

At a meeting of the Mombasa Division, held at Mombasa on July 9, with Dr. J. M. LISTON in the chair, Dr. G. V. JUYTAR showed a case of diabetes in a child of 6, and Dr. A. U. SHUTTI the following cases: (a) an unknown congenital disease of the bones; (b) hemiplegia in a child of 10; (c) chronic diarrhoea in a child of 2; and (d) silent coronary thrombosis in a man of 62.

NORTH OF ENGLAND BRANCH

At a meeting of the North of England Branch, held at Newcastle-upon-Tyne on October 16, with Prof. R. J. WILLAN in the chair, Mr. E. ROCK CARLING gave an address on "The Care of Air-raid Casualties." He outlined the scheme for the care of air-raid casualties from the time they were reported by the warden until they arrived at the stage of convalescence. He spoke from personal experience of the creditable way in which the rescue squads, first-aid parties, ambulance personnel, and reception hospital staffs carried out their duties, and he stressed the importance of the first-aid posts in relieving the casualty reception hospital of the care of trivial injuries, when all precautions were taken to avoid overlooking deeper underlying damage. At the reception hospital an amply large reception room, a well-equipped resuscitation ward, and adequate protected theatre accommodation were essential. Additional centres for specialized branches of surgery should be provided in accordance with the local needs and the staff available, and the policy of dispersal should be followed when practicable if the reception hospital was near to the danger area. In conclusion he paid tribute to the work of medical officers of health in the local organizations, and referred to the extensive investigations being done by the Medical Research Council with a view to improving the technique for the treatment of casualties. A vote of thanks to Mr. Rock Carling for his address, proposed by the president, Dr. F. W. GRANT, was enthusiastically supported by the meeting. After the address some demonstrations of orthopaedic cases were given by Mr. GORDON IRWIN and members of his clinic.

At a further meeting of the Branch, held at Newcastle-upon-Tyne on October 23, with Colonel W. WALKER, R.A.M.C., in the chair, Dr. T. A. MUNRO gave an address on "Mental Defect and its Military Significance." Dr. Munro said that men of low intellect, instead of being incorporated in the Army, should be given a suitable occupation by the Ministry of Labour, acting on the advice of a psychiatrist, because the feeble-minded not only made inefficient units in any combatant team but also hindered the working of others. After entry into the Army dullards should be grouped with men of like intelligence for work suited to their mental standard, usually of a non-combatant nature. A vote of thanks to Dr. Munro for his address was proposed by Dr. M. W. STEWART-SMITH and carried with acclamation. A number of ophthalmic cases were later demonstrated by Mr. J. S. ARKLE and Mr. A. MACRAE with their clinics.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Temporary Surgeon Lieuts. T. Pearce and E. R. Roseveare to be Temporary Surgeon Lieutenants.

ARMY

Major-General F. Casement, D.S.O., K.H.S., late R.A.M.C., has retired on retired pay, and remains employed.

Colonel (Acting Major-General) G. Wilson, O.B.E., M.C., late R.A.M.C., to be Major-General.

Colonel A. G. Biggam, O.B.E., K.H.P., late R.A.M.C., to be Major-General (supernumerary).

Lieut.-Colonel (Temporary Colonel) H. B. F. Dixon, M.C., from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Major (Temporary Lieut.-Colonel) D. Fettes, O.B.E., to be Lieutenant-Colonel.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major J. Charnley has relinquished his commission on account of ill-health, and retains the rank of Major. (Substituted for the notification in a *Supplement* to the *London Gazette* dated April 16, 1940.)

Supernumerary for Service with Edinburgh University (Senior Division) Training Corps (Medical Unit).—J. G. Slater to be Lieutenant.

Supernumerary for Service with Glasgow University (Senior Division) Training Corps (Medical Unit).—To be Lieutenants: J. W. Chambers and A. C. Lendrum.

Supernumerary for Service with Liverpool University (Senior Division) Training Corps (Medical Unit).—W. J. Dilling to be Lieutenant.

ROYAL AIR FORCE

ROYAL AIR FORCE VOLUNTEER RESERVE

Flying Officers J. F. Cooper, J. R. O'Dowd, A. M. Holsnell, R. E. W. Oliver, C. N. Faith, C. J. Griffin, R. H. Carpenter, and F. S. Kelleher to be Flight Lieutenants (War Substantive).

INDIAN MEDICAL SERVICE

Lieut.-Colonel H. E. Shortt, C.I.E., to be Colonel.
Lieut.-Colonels H. Chand, M.C., N. J. Gai, and C. N. Ganapathy, M.C., have retired.

Captain D. K. L. Lindsay to be Major.

EMERGENCY COMMISSION

W. N. O. George to be Lieutenant.

COLONIAL MEDICAL SERVICE

The following appointments are announced: J. W. P. Harkness, M.B., Ch.B., D.P.H., Director of Medical Services, Nigeria; J. B. Kirk, M.B., Ch.B., D.P.H., Director of Medical Services, Gold Coast.

POSTGRADUATE NEWS

The Fellowship of Medicine announces that an M.R.C.P. course in neurology will be given at the West End Hospital for Nervous Diseases on Tuesdays and Fridays at 3 p.m. from November 25 to December 19.

A military hospital medical society has arranged a week-end course in war medicine, to be held on Saturday and Sunday, November 29 and 30. On November 29, at 1.45 p.m., following an introductory address by the officer commanding, Colonel A. McKie Reid, there will be medical and surgical clinics, x-ray demonstrations, and a discussion on respiratory infections. On November 30, at 9.30 a.m., there will be skin demonstrations, and eye injuries and anaerobic infections will be discussed. At 2.15 p.m. the programme includes resuscitation, oxygen therapy, an otological demonstration, and recent advances in anaesthetics. The visiting lecturers will be Mr. B. W. Williams and Dr. S. C. Dyke.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetric and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m., Post-mortem Demonstrations. *Tues.*, 10 a.m., Paediatric Clinic, Dr. R. Lightwood; 11 a.m., Gynaecological Clinic, Mr. V. B. Green-Armytage. *Wed.*, 11.30 a.m., Clinicopathological Conference (Medical); 2 p.m., Lecture, Bacteriology of the Coli-Typhoidal Groups, Dr. M. Barber. *Thurs.*, 2 p.m., Dermatological Clinic, Dr. R. T. Brain. *Fri.*, 12.15 p.m., Clinicopathological Conference (Surgical); 2 p.m., Clinicopathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. Green-Armytage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*Brompton Hospital*, S.W.: Mon. and Thurs., 3 p.m., M.R.C.P. Course in Chest Diseases. *London Chest Hospital*, Victoria Park, E.: *Tues.*, 2 p.m., M.R.C.P. Course in Chest Diseases. *King Edward Memorial Hospital*, Ealing, W.: Sat. (Nov. 22), 2 p.m., M.R.C.P. Course in General Medicine.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Pathology.—*Tues.*, 2.30 p.m. Short papers by Dr. W. W. Kay, Dr. A. M. Barratt, Dr. M. Hynes, and Dr. E. B. Hudson. Demonstration by Dr. A. B. Rosher.

Section of Dermatology.—*Thurs.*, 2 p.m. Clinical Meeting.

Section of Orthopaedics.—*Sat.*, 11.15 a.m. Meeting at Orpington Emergency Hospital. Presidential Address by Mr. C. Lambrinudi: The Role of Orthopaedics in Medical Education. Papers by Mr. K. M. McKeown, Mr. J. S. Batchelor, Mr. T. T. Stamm, and Dr. E. J. Crisp. Cases will be shown in the afternoon.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Larbert (Stirlingshire) is vacant. Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by November 25.

APPOINTMENTS

HALLIWELL, ERIC O., M.R.C.P., Temporary Honorary Physician, Hull Royal Infirmary.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

DEATH

MONRO.—On November 3, 1941, at 7, Berwyn Road, Richmond, Surrey, James Donald Rae Monro, M.D., formerly of Muswell Hill, after a long illness, bravely borne.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 22 1941

SOCIALIZATION OF THE MEDICAL PROFESSION IN NEW ZEALAND

[FROM OUR CORRESPONDENT IN WELLINGTON]

The Social Security Act of 1938 made provision for taxation of 1s. in the £ on all wages and salaries for the purposes of "social security." This tax covered the cost of free treatment in public hospitals, maternity services, old age, invalidity, and unemployment pensions, free medicine from pharmacists, but not until now medical service in the homes of the people or at doctors' consulting rooms. [A full account of the working of the hospital and maternity services under the Act was published in the *Supplement* of March 23, 1940.]

Recently the Social Security Amendment Bill of 1941 was introduced, when the war situation was critical and when between one-quarter and one-third of the medical profession were serving in the Army over-seas or in camps in New Zealand. This amending Bill of 1941 contained briefly the following provisions: For the purposes of the Act the expression "general medical services" meant all proper and necessary services of medical practitioners for persons entitled to any of the benefits provided, except "medical services involving the application of special skill and experience of a degree or kind that general medical practitioners as a class could not reasonably be expected to possess."

The services excluded were the administration of anaesthetics, maternity services, and such other services as might be excluded by the Minister of Health by regulations. The fees were to be 5s. (equal to 4s. sterling) for a consultation at the surgery and 6s. 6d. for a visit, these payments to be made directly out of the Social Security Fund under Government control. Payment for mileage was to be at the rate of 1s. 3d. for every mile up to twenty miles; for distances of more than twenty miles the doctor might recover mileage fees from the patient. The medical officer of health was to decide in all cases if the attendance was necessary, and he was given power to disallow the claim wholly or partly. All claims for medical fees had to be sent to the M.O.H., and had to be accompanied by a certificate from the patient or some responsible person that the service had been performed. The amount paid out of the Social Security Fund as specified above had to be accepted by the doctor in full satisfaction of all claims. Under the Bill the Minister of Health was to decide which practitioners were to be classed as "specialists." Finally, except with the consent of the Minister no doctor could sue for fees. If the patient did not give the necessary certificate the Minister, if he thought fit, might authorize the doctor to sue for fees, but only at the rate of 5s., 6s. 6d., and for mileage. If any person, including the doctor, made a misleading statement he was liable to a fine of £100 or to imprisonment for twelve months.

Before this Bill was tabled a voluntary capitation scheme was introduced offering a capitation fee of 15s., but very few doctors accepted it: one of the few is reported to have put 6,000 patients on his list.

Successful Opposition

It is obvious that this Bill sought to abolish private practice and put the whole profession, except "specialists" in the meantime, under the control of the Minister of Health and his officers. The doctors would be on duty for twenty-four hours a day without holidays, and the most capable and experienced would receive the same payment as juniors and with never a hope of bettering their position. The B.M.A. protested against this coercive Bill, and public indignation meetings were held. The politicians throughout the controversy affected to believe that their scheme was akin to the British panel system. The New Zealand Branch of the B.M.A. put forward a scheme

much more liberal than the British one, with a high wage limit, and covering specialist services and preventive medicine.

Confronted by determined opposition the New Zealand Government changed front and brought forward new amendments which got rid of the most objectionable provisions of the Bill, but not quite all. These new amendments were passed by Parliament and are now law. They give doctors freedom to practise in the old way, but the fees are 7s. 6d. for a consultation at the surgery, 7s. 6d. for a visit, and 12s. 6d. for a visit at night or on Sundays. The doctor charges the patient on the basis of these fees, and the patient gets a receipt and recovers the amount paid from the Social Security Department or from a post office. There is nothing to prevent the doctor from charging more than these fees from patients who are able and willing to pay.

The two remaining objections to the modified Act are: (1) The fixing of doctors' fees by Parliament; to fix fees by Act of Parliament is unprecedented, and contrary to all trade union principles. The doctors have asked for a tribunal, which has not been granted. (2) One section of the community—namely, the medical profession—is debarred from access to the courts in respect of claims against patients for payments higher than those mentioned in the Act. This is also unprecedented and probably unconstitutional; at any rate, it will be generally conceded that it outrages the principles of British justice and strikes a blow at freedom.

The profession will probably not oppose the scheme and will find no fault with patients under allegedly "free" medical service obtaining a refund of 7s. 6d. a consultation from the Social Security Fund created from a 1s. in the £ tax. Under the amended law doctors of the Dominion will have no direct contact with the State, but they bitterly resent their fees being fixed by Parliament. Most of all they resent being denied access to the courts, especially when patients may still bring actions against doctors for alleged negligence. Therefore the medical profession cannot cordially co-operate.

Commenting on the Protection of Practices Scheme in Scotland the Executive Committee of the Scottish Association of Insurance Committees, in its report for 1940-1, states that the information at its disposal indicates that the scheme has been successful and its wide adoption has been beneficial to both committees and the medical profession. The Executive, however, has been unable to agree to the term "absentee practitioner" being applied to doctors who are incapacitated or have died in the ordinary course of Nature. It considers that death or permanent incapacity in the case of a doctor in whole-time emergency service is adequately covered by the present arrangements. A proposal to extend the period of temporary residence of insured persons from three to six months has been agreed to by the Executive and is being considered by the Department of Health. The Executive, with other interested bodies, has made repeated representations during the year to the Department of Health on the subject of the hospital waiting lists, and a scheme is now in operation which, according to some reports, is partially relieving the situation. Briefly the scheme aims at utilizing to a limited extent the E.M.S. hospitals. Doctors will send all cases to voluntary hospitals in the usual way; the subsequent transfer of cases (with the patient's consent) and admission to an E.M.S. hospital will be for the decision of the two hospitals concerned. Doctors will also refer acute surgical cases to voluntary hospitals in the first instance, but the medical superintendent may, at his discretion, divert them to an E.M.S. hospital. The Executive comments that the arrangements are involved and cumbersome, but it is too early yet to say whether they will be effective in reducing the waiting lists.

MEDICAL WAR RELIEF FUND.

TWENTY-FIFTH LIST

Previously acknowledged, £34,437 9s. 7d. and £100 3½%
Conversion Stock and £40 3% Defence Bonds

Individual Subscriptions

- £15 15s.—Drs. Moran, Cooper, and McCloy, East Loos.
£10 10s.—Lieut.-Colonel C. W. Gordon Bryan, R.A.M.C.

Total, £34,926 3s. 8d. and £100 3% Conversion Stock and
£40 3% Defence Bonds

Malaya Branch.—The following were the contributors to the donation of £321 3s. 6d. acknowledged in the Supplements of August 23 and September 20: Dr. W. L. Blakemore \$10; Sir David Galloway \$1,000; Dr. M. Hikosake \$20; Dr. A. Viswalingam \$25; Prof. J. K. Monro \$100; Dr. C. D. Williams \$200; Colonel W. H. Cornelius, R.A.M.C., \$10; Dr. H. O. Hopkins \$25; Dr. Loh Seng Tak \$20; Dr. Mona H. Whyte \$20.25; Dr. D. R. McPherson \$25; Dr. J. M. Milne \$10; Dr. Mona H. Whyte \$20.25; Dr. Eithel Morris \$50; Dr. S. C. Howard \$200; Dr. E. S. Lawrie \$100; Dr. E. Goldberg \$25; Dr. V. T. Patwardhan \$5; Dr. J. M. A. Lawson \$50; Dr. R. M. B. Lewis \$50; Dr. Margaret Gibson-Hill \$50; Dr. J. E. McMahon \$20.25; Dr. O. O. Fisher \$20; Dr. Ho Sul Khan \$25; Dr. A. S. McKern \$100; Dr. Tong Lai Yee \$15; Dr. L. Sammy \$10; Dr. W. S. Leicester \$10; Dr. Kwong Kim Cheong \$10; Dr. A. E. Bedell \$25; Dr. Lim Yew Poh \$10; Dr. L. MacKintosh \$25.25; Dr. E. D. Wolfe \$20.25; Dr. J. V. Landor \$25; Prof. E. K. Trautman \$10; Dr. J. M. Dugdale \$50; Dr. Chee Set Chew \$50; Dr. J. F. Mitchell \$25; Dr. C. Nadarajah \$5; Dr. P. E. F. Routley \$5; Dr. M. A. Gabriel \$10; Dr. H. R. Dive \$25; Mr. S. J. Campbell \$26; Dr. E. M. Rex \$50.31; the Hon. R. B. MacGregor \$25; Dr. B. Cross \$20.

Correction.—The amount credited to Dr. Russell Brain in the twenty-fourth list under "Practitioners in the area of the Marylebone Division" was incorrectly stated as £2 2s. The amount should have been stated as £5 5s.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

Surgeon Captain E. C. Holton, O.B.E., has been placed on the retired list.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieut. T. D. G. Wilson to be Surgeon Lieutenant-Commander.

Probationary Temporary Surgeon Lieuts. W. W. Hutton, R. St. C. Mooney, E. Kavanagh, A. W. Hagger, J. G. Reynolds, A. J. Innes, A. M. Desmond, G. C. Blackham, G. S. C. Sowry, H. H. Kirk, and A. P. Bates to be Temporary Surgeon Lieutenants.

ARMY

Colonel K. Comyn, late R.A.M.C., has retired on retired pay and remains employed.

Lieut.-Colonel (Acting Brigadier) W. G. Hartgill, O.B.E., M.C., from R.A.M.C., to be Colonel.

Major A. C. H. Gray, O.B.E., late R.A.M.C., has reverted to retired pay and resumes the rank of Colonel on ceasing to be re-employed.

ROYAL ARMY MEDICAL CORPS

Major (Temporary Lieut.-Colonel) T. Menzies to be Lieutenant-Colonel.

Lieut. J. P. Crawford to be Captain.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Captain K. L. O'Sullivan to be Brevet Major, under the provisions of Article 163, Royal Warrant for Pay and Promotion, 1940.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—Daily, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetric and Gynaecological Clinics and Operations. Daily, 1.30 p.m., Post-mortem Demonstrations. Mon., 2.30 p.m., Course on Operative Surgery in Wartime commences. Tues., 10 a.m., Paediatric Clinic, Dr. R. Lightwood; 11 a.m., Gynaecological Clinic, Mr. V. B. Green-Armytage. Wed., 11.30 a.m., Clinico-pathological Conference (Medical); 2 p.m., Lecture, Diagnosis of Typhoidal Disease, Dr. M. Barber. Thurs., 2 p.m., Dermatological Clinic, Dr. R. T. Brain. Fri., 12.15 p.m., Clinico-pathological Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. Green-Armytage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—Brompton Hospital, S.W.: Tues. and Thurs., 3 p.m., M.R.C.P. Course in Chest Diseases. London Chest Hospital, Victoria Park, E.: Thurs., 2 p.m., M.R.C.P. Course in Chest Diseases. King Edward Memorial Hospital, Ealing, W.: Sat., Nov. 29, 2 p.m., M.R.C.P. Course in General Medicine. West End Hospital for Nervous Diseases: Tues. and Fri., 3 p.m., M.R.C.P. Course in Neurology.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Odontology.—Mon., 2 p.m. Paper by Surgeon Lieut.-Commander (D) J. Bunyan: Treatment of Mouth Infections, with Particular Reference to the Use of Electrolytic Sodium Hypochlorite.

Section of Urology.—Thurs., 2.30 p.m. Discussion: Rupture of the Urethra and its Treatment. Openers, Mr. Clifford Morson, Mr. Charles Wells, and Mr. Hugh C. Barry.

Section of Disease in Children.—Fri., 2.30 p.m. Discussion: Effects of Wartime Rationing on Child Health. Openers, Dr. E. M. Widdowson, Dr. D. C. Wilson, and Dr. W. W. Payne.

Section of Epidemiology and State Medicine.—Fri., 3 p.m. Paper by Dr. Melville Mackenzie: Some Practical Considerations in the Control of Louse-borne Typhus Fever in Great Britain, in the Light of Experience in Russia, Poland, Rumania, and China. Dr. G. W. M. Findlay, Prof. P. A. Buxton, and others will take part in the subsequent discussion.

BIOCHEMICAL SOCIETY.—At Courtauld Institute of Biochemistry, Middlesex Hospital, W., Sat., 11 a.m. Discussion: The Mode of Action of Chemotherapeutic Agents. To be opened by Dr. G. M. Findlay.

CHADWICK TRUST.—At Westminster Hospital Medical School, 17, Horseferry Road, S.W., Thurs., 2.30 p.m. Dr. S. Ernest Dore: Advances in Dermatology during the Past Forty Years.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.—Mon., 3.30 p.m. Discussion on three short papers: Heart Attacks, by Dr. John Parkinson; Congenital Shortening of the Oesophagus, by Mr. V. E. Negus; and Regional Ileitis, by Mr. Guy Blackburn.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at St. Blazey (Cornwall) is vacant. Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by December 2.

B.M.A.: Branch and Division Meetings to be Held

STIRLING BRANCH.—At County Offices, Viewforth, Stirling, Sunday, November 23, 2.45 p.m. Dr. Charles Melville: General discussion on the post-war organization of the medical services of the county.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTHS

PARRY.—On October 25, at Penylan Nursing Home, Cardiff, to Margaret (née Edwards), M.R.C.S., L.R.C.P., wife of F/O Keith Parry, R.A.F.V.R. (Med.), a daughter.

WEDDELL.—On November 8, at Hagley, Worcs, to Margaret Weddell, M.B., Ch.B., wife of Ralph Weddell, a son.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 29 1941

INCOME LIMITS IN NATIONAL EYE SERVICE

RECOMMENDATIONS OF OPHTHALMIC GROUP COMMITTEE OF B.M.A.

A meeting of the Ophthalmic Group Committee of the British Medical Association was held on November 14 to consider the position in relation to the National Eye Service of the Government's proposal to extend the income limit for non-manual workers under the National Health Insurance Act from £250 to £420 per annum. Mr. N. Bishop Harman presided, and there was a full and representative attendance, fifteen members out of the total of seventeen being present. Dr. Alfred Cox attended as acting secretary of the N.O.T.B.

At its previous meeting in June the Committee decided, in view of the dissatisfaction of many ophthalmic medical practitioners at the inadequacy of the present fee, the increase in practice expenses, and the prospective inclusion of a new group of insured persons with higher incomes, to circularize practitioners on the National Eye Service list asking whether they were in favour of raising the fee in the case of incomes up to £420, with certain consequent questions. The results of the questionnaire, which revealed a very large majority in favour of raising the fee, were carefully considered by the Committee, but the question was now discussed *de novo* in view of the resolution passed by the Special Conference of Representatives of Home Divisions on September 11, that the inclusion of non-insured persons and dependants with incomes between £250 and £420 for treatment under the National Eye Service would create an unwarranted restriction on private practice and be an unfavourable precedent in future extension of specialist services.

In preliminary general discussion one member stated that during the last two years he had done a very large amount of half-guinea work, having assumed responsibility for the list of an absent practitioner, as well as taking many Service cases, and in the end he found that the amount received barely covered expenses. He moved (but subsequently withdrew his motion) that the fee be raised, irrespective of income limit, to one guinea. Another member could not agree to the universal application of the guinea fee. There were people to whom it would be a great hardship; on the other hand, there were people with incomes above £250 who could well afford more than half a guinea, and the inclusion of such people on the lists would take away a fair amount of private practice. It seemed to this member that there was something to be said for a sliding scale of fees, depending on income. He urged that until the armistice the present income limit be maintained—that is, £250—and that no change of policy be agreed to until all oculists, including men on Service, had been consulted.

The chairman said that he had endeavoured to ascertain from those who could speak for Approved Societies whether a distinction could be made, so far as ophthalmic benefit was concerned, between the existing group of insured members and the

new group, and he gathered that although such a distinction would be greatly disliked it would be possible to make it. He then put forward for discussion not a resolution but what he called a target, some parts of which were shot away as the discussion proceeded. He reminded the Committee that any recommendations they made must go before the Council of the Association at its meeting on December 10.

One proposal, which found little favour, was that the fee for insured persons below £250 should be 10s. 6d., but for non-insured 15s. 6d., the reason for the differentiation being that the latter did not have to pay certain insurance dues, and that for all above £250 the fee should be one guinea. It was also pointed out that there were a large number of people with unearned incomes up to £250, which meant that they had capital at the back of them: also that there were people whose incomes were nominally below that limit, but actually far in excess of it owing to allowances such as free rent, board and lodging, etc.

Eventually it was agreed to recommend the Council that until further notice the following conditions shall apply in connexion with the National Eye Service:

1. Insured persons whose incomes do not exceed £250 per annum and their dependants will be accepted for treatment at a fee of 10s. 6d. each.
2. Non-insured persons other than dependants mentioned in (1) above whose incomes do not exceed £250 per annum may be considered as applicants for treatment at a fee of 10s. 6d. each.
3. For all other insured persons (including all manual workers and voluntary contributors with an income exceeding £250) the fee for an ophthalmic medical examination shall be £1 1s. each person.
4. The fee for all persons who do not fall within the above categories shall be at the discretion of the ophthalmic medical practitioner.

The passage of these recommendations one by one through the Committee was practically unanimous, though one or two members demurred here and there, but when the recommendations were put as a whole they secured the approval of every member present. It was agreed that they be sent to all medical practitioners on the National Medical Eye Service list, and that an endeavour be made to elicit their replies before the meeting of the Council. The Committee also decided that its decisions, if approved by the Council and by practitioners on the National Eye Service list, should be conveyed to the Ministry of Health and to Approved Societies.

Conference with Association of British Ophthalmologists

A report was laid before the Committee of a recent conference between representatives of the Committee and of the Association of British Ophthalmologists regarding possible improvements of the present administration of the National Eye Service and associated matters affecting ophthalmologists in general.

The Committee agreed that two members of the Association of British Ophthalmologists be invited to attend its meetings as observers (several members of the Group Committee are also members of that Association). Certain matters brought forward at the conference were referred to the N.O.T.B., being questions of detailed arrangements for referring patients and for convenience in dealing with prescriptions. One member stated that sight-testing opticians appeared to be able to obtain their material more quickly than dispensing opticians, but experience in different parts of the country was shown to vary in this respect.

On the wider matter of possible impending changes in the conditions of medical practice, a member proposed that the Committee should proceed to formulate a scheme for the ophthalmic examination and treatment of the community. It was pointed out, however, that one of the committees of the Medical Planning Commission was concerned with special practice, and should it appear to them that ophthalmic problems called for special consideration apart from those affecting other specialist sections of the profession, the matter would doubtless be referred to the Group Committee. The member professed himself satisfied and withdrew his proposal.

The final matter dealt with by the Committee concerned the employment of sight-testing opticians by certain industrial organizations. On this it was pointed out from the chair that whatever might be the position in certain individual factories, the propaganda work of the N.O.T.B. had undoubtedly taught those in control of factories that all their examinations should be carried out by medical men. Attention was drawn to the report, just issued, of the Industrial Health Committee of the Association, and the propositions there put forward, which, the chairman said, if carried through would ensure that eye work in the factories in the future would be carried out on proper lines.

Reorganization of hospital services and a State Medical Service were the subjects discussed at the health session of a recent conference at Bath on the reconstruction of post-war Britain. Mr. R. S. Trueman, in an opening address, said that one of the difficulties of our present hospital system was the inadequate provision for the middle classes. The rich and poor were catered for, but treatment for the middle classes depended on how much could be spared from the family budget. He advocated a Royal Commission of five members, all under 40 years of age, to consider the problem. What was needed, he said, was a national hospital system on a regional basis, each region run by a hospital officer. Staff appointments should be made by a board of university professors of medicine; hospitals should be enlarged and opened to all classes, each patient paying what he could afford; and all nursing homes should be closed. Mr. Trueman considered that voluntary hospitals "were finished and should become State-controlled," but earlier in his address he had entered a caveat that "the Civil Service should be prevented from playing ball with proposals put to them." Mr. C. E. Kindersley considered that planning should be on what we have at present: we should not try to sweep away the voluntary hospitals, which were some of the biggest institutions in the country. Hospitalization had to be paid for by taxation and by voluntary effort, and in his view it should be by "a little of both." The medical profession should get on with its job—the investigation and treatment of disease, and, if possible, its prevention. There was no greater damper to enthusiasm than bureaucratic control. Miss Maud Forrester-Brown contended that industry should carry the cost of the health of its population, while Dr. Elizabeth Casson appealed for an organized mental health scheme. Summing up the debate, Dr. Barnes Burt deplored the suggestion that doctors should become civil servants. In a State Medical Service on the lines of the Civil Service, promotion, he said, would be by seniority. Moreover, a board sitting in London could know nothing of local medical men and conditions. In his view a State service run entirely by Whitehall would be a failure.

Correspondence

Capitation Fee

SIR,—I read Dr. Douglas's letter in the *Supplement* (November 1, p. 87) and found it most interesting. I fail to see how the B.M.A. can reconcile its advice to practitioners to increase their private fees by 20% with the action of the committee in accepting a paltry 9d. a head increase in the capitation fee, more especially since the latter was far too low before the war.

Since the war began wages of all workers have been increased or bonuses given to meet increased costs of living, yet the B.M.A. appears to refuse to make a firm stand to obtain even adequate remuneration for its members, who have, in addition to the ordinary increased costs of living, also the increased costs of running practices and of additional unpaid work. As an example of the latter I will mention only two instances: attendance on the wives and families of men in the Forces, who out of their Army allowance cannot afford to pay ordinary fees, let alone with a 20% addition; and, secondly, the increased number of certificates we are bound to give, in the majority of cases free of charge. If the Government want people to get certificates for milk, clothing, war injuries, etc., free of charge they should be prepared to pay practitioners a fee for these certificates. And while we are on the subject of certificates, may I point out how some local authorities deliberately give us extra and absolutely unnecessary work. As illustration I will cite only one recent case. I gave a certificate to an expectant mother to obtain coupons for the baby's clothing; this was returned to her with an official form to be again signed by me, and yet all the information required on the official form had been given in my certificate! If local authorities have time and paper to waste in this manner it should be explained to them that medical practitioners have not.

As the vast majority of practitioners are very dissatisfied with the proposed increase in the capitation fee and with the inclusion of those with incomes up to £420 a year in national health insurance, also with the absence of a wartime bonus, why do they not unite together and send a petition to their local Panel Committee, with copies to the B.M.A. and Ministry of Health, requesting revision of the capitation fee at once and postponement of inclusion of the higher-wage earners until after the war, at the same time pointing out that the inclusion of the higher-wage group would be infringement of our contract, and that if satisfactory terms were not granted we should all terminate that contract? It is up to us to do this, and surely it is about time we did show that we are able to present as united a front as any other body of workers.—I am, etc.,

Wetherby, Nov. 5.

S. TERRY PYBUS.

SIR,—Before accepting new terms for national health insurance work attention must be paid to the financial aspect as it affects practitioners. It should not be impossible to employ well-qualified actuaries, as all insurance companies do, to investigate the amount of work likely to be incurred and the premium per insured person that would honestly remunerate the doctor for his services. There must be no guessing. It is obvious that each client accepted under N.H.I. is lost to private practice, and if there is a discrepancy the profession will suffer proportionately. Has any comparison between N.H.I. and private practice been made? Twenty-eight years' experience since 1913 should make that possible.

My panel is very small—assessment easy—and on calculating for last month I find that in the borough it works out at 10½d. per attendance, including visits, and in the country, where mileage is not allowed, the return is nil, as petrol consumption absorbs the pay; only my private practice enables, nay, compels, me to undertake this work. There cannot be two standards of work.

Recently the local Division asked us to conform to this minimum scale of charges for adults from January 1, 1941: Consultation at the surgery, with medicine, 6 oz., 3s. 6d.; visit, 3s.; visit with medicine, 6 oz., 6s. 6d.; special visit up to 10 p.m., 5s.; night visit, 10s. 6d.; and add 20% to each account

during the war. If the remuneration I am receiving from the State were fair these charges would be preposterous, which is absurd.

It would be more reasonable if the B.M.A. insisted on all members conforming to just and equitable fees, not only for the dependants but for the workers themselves, including contract practice, otherwise we may find ourselves in a worse position than the old sixpenny doctor, for the tanner of 1900 was worth as much as the bob of to-day. The old "sixpennies" did no book-keeping, and had no bad debts and no Gestapo. I rather fear that our leaders are idealists, and would have us rise to the high standard of the Greeks, but those Greeks were men of independent means when living was cheap. We live in a very different world of business facts.—I am, etc.,

Bolton, Nov. 7.

WM. HARVEY BENNETT.

State Medical Service

SIR—I have read most of the correspondence on this subject, and I have been quite unable to discover what is meant by a "State Medical Service." I doubt, indeed, whether either its advocates or its opponents are quite clear about the matter.

Before a rational discussion can take place on any subject it is first necessary to define that subject, and my object in writing is to try to extract from the sponsors of the idea an unequivocal statement on the exact extent of what they call a State Medical Service. To me the term implies that the whole medical profession with its auxiliaries—hospitals, dentists, nurses, opticians, pharmacists, etc.—should become salaried servants of the State to be used in any capacity for which the State may deem them fitted; that the individual subject should become the patient of the State and should be treated by the doctor detailed for the purpose in such manner as may be prescribed by the State; that the practice of healing, whether qualified or not, by other than State servants and the sale of appliances and substances used in the treatment of disease should be prohibited.

A "State" Medical Service can, logically, mean no less than this, but it is possible and, indeed, probable that the enthusiasts may mean a good deal less. Perhaps one of them will be tempted to tell us what modifications, if any, of the above may be in their minds.—I am, etc.,

Jarrow-on-Tyne, Nov. 17.

F. W. GRANT.

B.M.A. : Meetings of Branches and Divisions

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION

At a special meeting of the Bournemouth Division, held at Boscombe on November 5, with Dr. A. R. N. MACGILLYCUDDY in the chair, Sir ROBERT ARCHIBALD, Group Co-ordinating Officer for the Casualty Services in the Bournemouth, Poole, and Christchurch Joint Area, and adviser on these services to the Group Controller, gave an address on "The Medical Organization of the Civil Defence Services for the Area."

Sir Robert first described the administrative side of Civil Defence. He then referred to invasion, and outlined the action which doctors would have to take. Practitioners going to an air-raid "incident," he said, should always report to the "incident officer," whose whereabouts would be clearly indicated. After the address several questions were put to Sir Robert, one or two practitioners stating that they were still not clear as to what part they would have to play in an invasion. Sir Robert suggested that any practitioner who wanted information on any one definite point should write to him, and if he was unable to answer it himself he would try to get a ruling.

A hearty vote of thanks was accorded to Sir Robert Archibald for his address.

GLASGOW AND WEST OF SCOTLAND BRANCH

The Glasgow and West of Scotland Branch had a very successful meeting on November 2, when Prof. C. F. W. ILLINGWORTH gave a lecture on "The Treatment of Air-raid Casualties." The attendance was about 200, and a collection which was made afterwards resulted in a substantial sum being sent to the Royal Medical Benevolent Fund.

NORTH OF ENGLAND BRANCH

At a meeting of the North of England Branch, held at Newcastle-upon-Tyne on October 30, with Mr. T. A. HINDMARSH in the chair, Mr. L. R. BROSTER read a paper on "Some Biological Aspects of

War." He likened a nation to a body composed of cells, each with a part to play, and upon the harmonious working of which the survival of the whole depended. Discord would lead to disruption. In man, he said, conduct depended on inherited instinct and environment, and in a civilized community primitive impulses such as rage and terror were normally kept under control beneath intelligent behaviour. In time of war such qualities as discipline, endurance, courage, and self-sacrifice arose, but these were to a great extent overshadowed by the primitive conflicting urges—such as anger, pugnacity, brutality, and destruction—then roused. Propaganda stimulated rage on one side and fear on the other. The herd instinct tended to bring peoples together for their mutual protection, while fear and intense nationalism both kept them apart and prevented a united stand against a common enemy. A vote of thanks to the speaker was proposed by Dr. C. N. ARMSTRONG and enthusiastically supported by an appreciative audience. After the lecture a demonstration of methods of resuscitation was given by Dr. T. H. BOON and members of his clinic.

STAFFORDSHIRE BRANCH: NORTH STAFFORDSHIRE DIVISION

There have been several successful meetings of the North Staffordshire Division, as follows: September 28, address by Prof. A. D. MACDONALD (Manchester) on "Drugs: The Present Position and the Outlook"; October 19, Dr. A. LINE (Birmingham) on "The Clinical Aspects of Air-raid Casualty Work in the Aid Post"; October 26, Prof. SEYMOUR BARLING (Birmingham) on "The Treatment of Shock in Air-raid Casualties." The sum of £17 was collected at the last two meetings for the R.M.B.F. Christmas Fund, and a further collection was made on November 2, when Dr. S. WARD (Birmingham) gave an address.

SUFFOLK BRANCH: EAST SUFFOLK DIVISION

At a meeting of the East Suffolk Division, held at Ipswich on September 26, with Dr. K. W. MACKENZIE in the chair, Prof. J. A. RYLE gave a lecture, by arrangement with the Ministry of Health, on "Gas Poisoning (Phosgene and Mustard): Clinical Recognition, Complications, Treatment, Sorting, and Evacuation." On the motion of Dr. F. R. STANSFIELD, seconded by Dr. J. W. HUNTER, Prof. Ryle was accorded a hearty vote of thanks for his address.

Medical Forces of H.M. Services Appointments

ROYAL NAVY

Surgeon Lieuts. C. J. P. Pearson, I. C. MacDonald, F. W. Baskerville, P. G. Burgess, and W. H. C. M. Hamilton to be Surgeon Lieutenant-Commanders.

ROYAL NAVAL VOLUNTEER RESERVE

T. Thornton to be Temporary Surgeon Lieutenant-Commander. Probationary Temporary Surgeon Lieuts. A. L. Phillips, J. M. Williams, and C. Remington-Hobbs to be Temporary Surgeon Lieutenants.

ARMY

Colonel R. J. Blackham, C.B., C.M.G., C.I.E., D.S.O., retired pay, late R.A.M.C., has been granted the local rank of Major-General.

ROYAL ARMY MEDICAL CORPS

Major D. Fettes, O.B.E., to be Lieutenant-Colonel. (Substituted for the notification in the *Supplement* to the *London Gazette* dated October 31, 1941.)

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel A. MacG. Duff, M.C., from supernumerary for service with O.T.C., to be Lieutenant-Colonel, next below Lieut.-Colonel R. I. Poston. (Substituted for the notification in the *Supplement* to the *London Gazette* dated October 6, 1939.)

Lieut.-Colonel G. P. Crowden, from supernumerary for service with O.T.C., to be Lieutenant-Colonel. (Substituted for the notification in the *Supplement* to the *London Gazette* dated October 6, 1939.)

Captain (now Temporary Major) N. J. Logie, from supernumerary for service with O.T.C., to be Captain, next below Captain W. S. Harvey. (Substituted for the notification in the *Supplement* to the *London Gazette* dated October 6, 1939.)

Captain (now Temporary Major) I. Gordon, from supernumerary for service with O.T.C., to be Captain. (Substituted for the notification in the *Supplement* to the *London Gazette* dated October 10, 1939.)

The notifications regarding the transfer of the following officers from T.A.R.O. in the *Supplements* to the *London Gazette* dated as follows are cancelled: September 14, 1939.—Captain R. A. M. Scott and Lieut. (War Substantive Captain) (now Temporary Major) D. L. Grieg. October 10, 1939.—Lieut. (War Substantive Captain)

(now Temporary Major) R. E. Pleasance, and Lieut. (War Substantive Captain) L. H. Crosskey. October 17, 1939.—Captain H. Miller. November 1, 1939.—Lieut. (War Substantive Captain) (now Temporary Major) E. A. Sparks. November 15, 1939.—Captain (now Temporary Major) E. A. Downes, and Lieut. (War Substantive Captain) (now Temporary Major) H. R. Vernon.

War Substantive Captain G. W. Campbell has relinquished his commission on account of ill-health, and has been granted the rank of Major.

Supernumerary for Service with Edinburgh University Contingent, Senior Training Corps (Medical Unit).—J. B. Borthwick to be Lieutenant.

Supernumerary for Service with Leeds University Contingent, Senior Training Corps (Medical Unit).—W. E. Adams to be Lieutenant.

Second Lieut. P. Turner, from Royal Artillery, Territorial Army, to be Lieutenant. (Substituted for the notification in the *Supplement to the London Gazette* dated June 20, 1941.)

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel A. H. D. Smith, M.C., T.D., has relinquished his commission on account of ill-health, and retains his rank.

War Substantive Lieut. S. E. Kraul has resigned his commission.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

G. Riddoch to be Lieutenant, and is promoted to the rank of Acting Colonel.

War Substantive Captains A. M. Brannan, W. T. Andrews, L. M. Curtis, R. Wylie-Smith, and D. G. Price have relinquished their commissions on account of ill-health and retain their rank.

The notification regarding Lieut. R. Hunter in the *Supplement to the London Gazette* dated March 5, 1940, is cancelled.

Lieut. T. G. Wilson has relinquished his commission on account of ill-health and retains his rank.

Lieut. M. G. Valentine has relinquished his commission on account of ill-health.

To be Lieutenants: R. F. de Luz, A. I. Bowie, J. L. Douglas, J. B. Adam, P. B. Angus, R. G. Benians, J. R. Borg, J. Breckenridge, A. Brown, J. Bruce, W. D. Buchanan, G. V. Burns, A. H. Campbell, J. C. Comline, P. Cosgrave, J. Crealey, B. R. Cumbo, W. J. Curran, E. M. E. Decottignies, S. Ellenbogen, C. Exell, J. L. Grant, H. G. Griffin, R. S. B. Hamilton, G. Harkness, A. E. T. Hart, J. R. Hewitt, E. Hindon, G. B. Hirst, C. E. Holden, F. L. Ingram, J. G. Jones, W. K. Laing, J. T. A. Lloyd, J. T. MacBrayne, T. B. S. McDougall, G. D. H. McQuitty, R. N. Mathur, T. Miles, R. H. B. Mole, I. W. Monie, A. J. Moss-Blundell, J. P. J. Paton, R. Percy-Lancaster, L. D. Philp, R. G. Richards, C. W. R. Roseby, R. A. Sammons, R. S. Saxton, L. J. Segal, A. G. Smith, E. R. Smith, A. L. B. Stevens, W. Stewart, T. S. Stone, M. G. Sutton, T.-L. Tan, R. W. Tibbets, W. R. Trotter, E. G. Tuckwell, H. Walmsley, J. Wills, H. M. O. Wolff, H. D. Wyse, P. T. Yonge, C. A. Young, R. M. Young, J. A. Reid, J. H. Strahan, O. F. Warner, J. K. Slater.

Dr. G. A. Johnson, Medical Officer with the relative rank of Lieutenant, has relinquished her appointment on account of ill-health.

The following have been granted Emergency Appointments as Medical Officers with the relative rank of Lieutenant: Elizabeth M. Rees, Esme M. Grant, Margaret J. Honeywill, Kathleen Neville, and Thelma M. Ward.

ROYAL AIR FORCE

Miss B. A. Briant and Miss A. C. Clark have been promoted to the relative rank of Flight Lieutenant (War Substantive).

To be Medical Officers (Emergency) for employment with the R.A.F. with the relative rank of Flying Officer: Barbara S. Gordon, Mary E. G. Sherwell, Rhoda M. Taylor, Molli C. Walsh, Daphne Smith, and Clarice Hughes.

RESERVE OF AIR FORCE OFFICERS

Flight Lieut. J. F. S. Wiseman has relinquished his commission on completion of service.

ROYAL AIR FORCE VOLUNTEER RESERVE

R. R. Macintosh to be Group Captain (Emergency).
To be Flight Lieutenants (Emergency): C. P. Petch and S. S. Yudin.

Flying Officers R. McP. Cross, T. E. Whitby, C. G. Bisley, J. V. O'Sullivan, C. D. Cormac, J. C. Bryce, J. C. Howitt, W. Huey, A. F. Rutherford, A. L. Basham, A. H. Pritchard, B. J. O. Winfield, W. B. Parker, L. J. Simon, R. Cargill, H. B. Forrest, A. Greenwood, D. P. Harris, R. W. J. Maclure, J. W. Magill, E. F. Mulcahy, M. M. Fraiss, R. M. Corker, and I. A. Donaldson to be Flight Lieutenants (War Substantive).

Flying Officer K. Froome has relinquished his commission on account of ill-health and retains his rank.

To be Flying Officers (Emergency): J. H. B. Cantley, D. McCaw, I. B. Millar, M. Gold, C. M. Liddell, W. N. Maclay, J. F. Martin, A. R. Nettleton, W. T. Ross, and S. T. Winter.

INDIAN MEDICAL SERVICE

Major-General (local Lieut.-General) W. H. Hamilton, C.B., C.I.E., C.B.E., D.S.O., K.H.P., has retired.

Lieut.-Colonel G. Covell, C.I.E., to be Colonel.

Major P. V. Karamchandani to be Lieutenant-Colonel.

Captains J. D. Murdoch, R. D. MacRae, A. T. Andreasen, D. G. McCaully, R. K. Muir, W. S. Morgan, M. S. Purvis, and M. E. Kirwan to be Majors.

EMERGENCY COMMISSIONS

Lieuts. W. H. S. St. John-Brooks, J. M. French, M. Shaw, W. R. Smith, G. C. Tresidder, and R. H. Vasey to be Captains.

To be Lieutenants: D. S. M. Euraght-Mooney and M. Seager.

COLONIAL MEDICAL SERVICE

The following appointments are announced: J. H. Bowyer, M.B., B.Ch., D.P.H., Superscale Officer, Grade A, Malaya; T. C. Wakefield, M.B., Ch.B., Superscale Officer, Grade B, Malaya; J. O. Shircore, M.B., Ch.B., Medical Officer, Nyasaland.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL ASSOCIATION, 10 a.m. to 4 p.m., 100, Regent Road, W.—Daily, 10 a.m. to 4 p.m., Clinics and Operations, Obstetric and Gynaecological Clinics and Operations. Daily, 1.30 p.m., Post-mortem Demonstrations. Tues., 10 a.m., Paediatric Clinic, Dr. Lightwood; 11 a.m., Gynaecological Clinic, Mr. V. B. Green-Armytage. Wed., 11.30 a.m., Clinico-pathological Conference (Medical); 2 p.m., Lecture, Pathology of the Intestinal Tract (II), by Prof. J. H. Dible. Thurs., 2 p.m., Dermatological Clinic, Dr. R. T. Brain. Fri., 12.15 p.m., Clinico-pathological Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. Green-Armytage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—Brompton Hospital, S.W.: Tues. and Thurs., 3 p.m., M.R.C.P. Course in Chest Diseases. West End Hospital for Nervous Diseases: Tues. and Fri., 3 p.m., M.R.C.P. Course in Neurology.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—Tues., 3.30 p.m. Candidates for election to the Fellowship.

Section of Surgery.—Wed., 2.30 p.m. Discussion: Effects on the Kidney of Trauma to Parts other than the Urinary Tract, including Crush Syndrome. Openers, Dr. E. G. L. Bywaters and Mr. R. Belsey, followed by Dr. J. McMichael, Mr. D. H. Patey, and Mr. V. H. Riddell.

Section of History of Medicine.—Wed., 2.45 p.m. Exhibit by Dr. J. F. Halls Dally: Portrait in oils of Sir Astley Cooper (1768-1841), painted by Daniel Maclise, R.A. Paper by Mr. C. E. Elcock: Hospital Building—Past, Present, and Future. Members of the Section of Epidemiology and State Medicine are specially invited to attend the meeting.

Sections of Laryngology and Otology.—Fri., 10.30 a.m. Discussion: Effects of Flying on the Nose and Ear. Opening papers by Wing Commander J. F. Simpson, Group Captain E. D. D. Dickson, and Squadron Leaders D. B. Fry, J. E. McGibbon, and R. H. Winfield.

Section of Anaesthetics.—Fri., 2.30 p.m. Discussion: Present Position of Ether. Openers, Dr. Z. Mennell and Dr. R. Jarman.

ROYAL INSTITUTION, 21, Albemarle Street, W.—Tues., 2.30 p.m., Prof. J. C. Drummond: Recent Advances in the Science of Nutrition and their Significance in Wartime. Thurs., 2.30 p.m., Prof. Benjamin Farrington: The Hand in Healing: A Study in Greek Medicine from Hippocrates to Ramazzini.

APPOINTMENTS

BINICLIFFE, E. W., M.S., F.R.C.S., Senior Surgeon, Rinkwood Hospital, Worcester.

LONDON COUNTY COUNCIL.—The following appointment in the Council's mental health services has been made at the hospital indicated in parentheses. Temporary Specialist: D. Shaw, M.D., M.R.C.P. (Sutton Emergency).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

MARRIAGE

WILKIE—DUFFY.—On November 29, at Upminster, Essex, Duncan Richard Primrose Wilkie, Captain, R.A.M.C., to Mary Duffy, S.R.N.

Correction

Through a printer's error the list of equivalent drugs published in the *Supplement* of November 15 (p. 91) states that diphenan is identical with albucid. The equivalent of albucid is sulphacetamide.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 6 1941

INSURANCE ACTS COMMITTEE OF THE B.M.A.

ECONOMIC POSITION OF INSURANCE PRACTITIONERS

A fully attended meeting of the Insurance Acts Committee was held on November 20, with Dr. E. A. Gregg, who was unanimously re-elected to that position, in the chair. In reappointing the Executive Committee three new members (Dr. T. A. Rogers, Dr. S. Wand, and Dr. J. B. Wilson) were added, making nine in all. The various resolutions of the recent Special Panel Conference and the still more recent Conference of Representatives of Home Divisions, all bearing on the insurance capitation fee and the revision of the income limit for non-manual workers, were before the Committee. There were also other resolutions and communications from Panel Committees and Divisions, some of them criticizing the action taken by the Insurance Acts Committee in recent events.

Contact with the Individual Practitioner

Before these were considered the question was raised by one member to what extent members of the Committee were accustomed to meet their constituents. Of the members of the Committee, twenty-six represent the seventeen groups of Panel Committees covering Great Britain and Northern Ireland, and it was felt that if the members met their constituents in their respective groups, gave them an account of their stewardship, and informed them of the progress of any negotiations, a great deal of suspicion would be allayed and misunderstanding avoided—in other words, that lack of contact, not negligence or lack of wisdom in the handling of the main business, was the cause of existing friction. Members were reminded that group machinery was in existence, although it appeared to be unused in many areas, members meeting their own Panel Committee but not the group. It was agreed that the group machinery should be overhauled.

The Isle of Wight Panel Committee suggested a personal communication at regular intervals from the Insurance Acts Committee to each individual practitioner regarding any major issue likely to come forward for consideration. In this connection the Secretary (Dr. Anderson) said that, acting on the instructions of the Executive Committee of the Association, he had recently addressed a letter to every member, and he hoped to send a copy of the letter also to insurance practitioners who were not members. It was recognized that in the absence of the normal number of meetings some such method of spreading information was desirable.

One point of obvious misunderstanding appeared in a resolution from the Norfolk Panel Committee, wherein dissatisfaction was expressed at the action of the Insurance Acts Committee, in "recommending" a capitation fee of 9s. 9d. The Committee, of course, made no recommendation to the Conference, and had previously made it abundantly clear to the Minister that it would not do so.

Question of Cost-of-living Bonus

The chairman reminded the Committee of the three aspects of the situation from the economic point of view: the first, a reconsideration of the basic capitation fee, which was promised, without delay, immediately after the war; the second, an increase due to the rise in cost of living (it had been promised that this would be dealt with when such an increase was given to comparable sections of the community); and the third, an increase due to rising practice expenses, which had already been obtained. Practice expenses, however, were still rising, and it might be necessary to ask for a further increase under this head.

With regard to a cost-of-living bonus, it was explained that "comparable sections of the community" meant persons of like economic status to general practitioners. The Deputy Secretary (Dr. Hill) said that at the time when the Executive began its consideration of this subject the upper salary limit of Government employees who were receiving bonus was £250. During the discussions, however, it rose to £350 and since the Conference it had risen to £500. Taking 100 as representing the cost of living in July, 1914, the figure in August, 1939, was 155, in January, 1940, it had risen to 174, in September, 1940, to 187, and at the present time it stood at 200. The index figure for working-class families had risen by 45 points, or 29%, since the outbreak of the present war, and the increase for middle-class families would be approximately one-half of that, though this would need to be recalculated. It was also stated that in the last war the first war bonus, a differential one of 12½% where the net income did not exceed £500, and of 10% for incomes between £500 and £1,000 (with a £60 maximum), was not given until the last year of the war, 1918.

It was agreed that a case might usefully be presented for consideration, even if only for a section of the profession, and the Executive was requested to explore the matter and lay proposals before the next meeting.

Consultation with the Profession

One matter of complaint in certain of the resolutions concerned the lack of consultation by the Ministry with the representatives of the profession regarding the proposed inclusion of the higher income group. The chairman stated that when the deputation met the Minister of Health they told him frankly of this dissatisfaction, and in the most explicit way he expressed regret and gave assurances. It was pointed out, however, that the present Minister and his advisers would not always occupy their present positions, and it was thought well to have a resolution asking for the assurance not of the present Minister but of the Ministry that adequate opportunity would be given for consultation in the event of any future change in which the medical profession was affected. It was explained that by "consultation" was meant not only consultation with the Committee but opportunity for consultation with the Committee's constituents.

It was decided that such a resolution deserved specially careful drafting, and it was remitted to the next meeting for this to be done. A request by the Glasgow Panel Committee for a full inquiry into the machinery of collective bargaining was also remitted to the Executive.

On another resolution, this time from Stoke-on-Trent, a member of the Committee asked whether there was any plan of campaign at headquarters in case practitioners wished at any time to refuse service. The need for more publicity in order to ensure an understanding in the minds of the public of the profession's case was also ventilated. The comprehensive publicity campaign which was prepared before the war has necessarily had to be placed in cold storage. The Committee thought it desirable that a plan of campaign should be considered by the Executive. It was mentioned that the last such plan was evolved in 1917.

Medical Benefit for Dependents and for War Workers

On the question of bringing in dependants of insured persons, the feeling of the Committee appeared to be—and it was said

COURSE FOR HOME GUARD MEDICAL OFFICERS

A further course for medical officers of the Home Guard has been arranged to take place at St. John's College, Cambridge, from December 18 to 23, 1941, inclusive. The places in this course will be filled from unsuccessful applicants for the September course, and no fresh applications can now be considered. Successful applicants have been communicated with direct through military channels.

RANK OF HOME GUARD BATTALION MEDICAL OFFICER

In August last instructions were issued by the War Office stating that the rank of battalion medical officer should be that of major, *or such lower rank as may be considered desirable*. In October, however, the War Office rectified the position by stating that battalion medical officers should hold the rank of major.

Correspondence**Democratic Machinery**

SIR,—The B.M.A. Secretary's call for greater trust in our elected representatives does not reduce my fear of cavalier treatment by the Ministry of Health. Our position might be improved if he recognized what Ministers of Health seemed to know—that our democratic machinery is decrepit.

Annual general meetings of a B.M.A. Division largely consist of committee-men re-electing themselves. The silence of their constituents gives consent.

A meeting of panel doctors, called to consider the proposed ninepenny increase of the capitation fees, had little to say. After the mover of rejection had summed up, the panel representative in the chair urged the meeting to accept the offer. It is not likely that the mover of the motion will again accept an invitation from the chair to break the silence that gives consent.

Satisfied and dissatisfied doctors alike silently allow our democratic machinery to rust. Chairmen, secretaries, and other elected representatives inevitably grow to resemble autocrats. Astute bureaucrats take advantage of this.

Perhaps a cause of this dangerous decline of democratic practice is our excessive acceptance of the priestly role imposed on doctors by their patients. Mere deacons and priests might maintain our decorous silence in the presence of high priests. If the suggestion that specialists are, after all, more akin to dentists than to doctors produces a reaction such as blasphemy might elicit, then it may be suspected that fundamentally we are at the mercy of high priests and hampered by hypocrisy and its attendant corruption.

Our situation might be improved if matters of importance were habitually decided by the postal votes of all doctors concerned, and if more and smaller branches of the B.M.A. were encouraged to cherish the privileges and duties of democracy.—I am, etc.,

Llanbadach. Glam. Nov. 27.

WILLOUGHBY CLARK.

Supplementary Milk Certificates

SIR,—Could something be done to bring to an end the most unsatisfactory state of affairs which now exists in the matter of the signing of these certificates? The public are told that if they are ill they can get an official form signed by their doctor, which, when presented to the local Food Office, will enable them to get extra milk. Actually this is entirely erroneous, as the doctor is only allowed to sign these certificates if the patient is suffering from a scheduled disease. The fact that the patient has been ill for a long time, or that the doctor thinks the patient ought to have more milk, is not recognized by the Minister of Food as sufficient reason for the patient to have extra milk unless the ailment from which he is suffering is in the short list of diseases which the Minister of Food has placed on his schedule.

In actual fact, therefore, all that a doctor is allowed to do is to decide whether a patient's disease is, or is not, on the official schedule, and beyond this he has no power to influence the supply of milk. A doctor, therefore, should not have to fill

in milk forms at all, but simply give the patient who asks for it a statement saying that his ailment is, or is not, on the list of specified diseases, and all the rest of the work entailed, whether in discussion or in the filling in of forms, should be done at the local Food Office by the officials who are paid to do this work.

As things are at present, general practitioners are being regarded by the public as autocratic and heartless in their refusal to give milk certificates to those of their patients who think they ought to have them, and this bad feeling is growing daily, while an enormous amount of precious time is wasted in discussion, simply because the doctor is trying to carry out conscientiously the official instructions, he has received personally.—I am, etc.,

Slough, Nov. 27.

H. TUDOR EDMUNDS.

WEEKLY POSTGRADUATE DIARY

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Birmingham North (Warwickshire) is vacant. Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by December 16.

APPOINTMENTS

HODGE, R. Sessions, M.R.C.S., L.R.C.P., Consultant Psychiatrist to Somerset County Council.

B.M.A.: Branch and Division Meetings to be Held

METROPOLITAN COUNTIES BRANCH: WESTMINSTER AND HOLBORN DIVISION.—At B.M.A. House, Tavistock Square, W.C., Friday, December 12, 1.30 p.m., General meeting. Brigadier J. C. A. Dowse (Inspector of Medical Services) and Dr. E. A. Gregg: "Medical Man-power."

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTHS

AIREY.—On November 25, at Stoneygate Nursing Home, Leicester, to Florence Anne, wife of Francis Stuart Airey, M.B., Ch.B., M.R.C.P.Ed., a son.

HAYWARD-BUTT.—On November 11, 1941, at Doocot Park, Crail, Fife, to Kay (née Howarth), wife of Surgeon Lieutenant Peter Hayward-Butt, Royal Navy, a son.

SHAW.—On November 21, 1941, at the Grange Nursing Home, Berkhamsted, to Daphne (née MacColl), wife of Dr. C. Carter Shaw, a son.

DEATH

NASH.—On Friday, November 28, Elwin Harral Thomas Nash, M.R.C.S., M.R.C.P., D.P.H., aged 69, for forty-two years much-loved husband of Mary Monica Nash. Any communications to Beaumont Flat, Canford School, Wimborne, Dorset, telephone Wimborne 166.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 13 1941

GENERAL MEDICAL COUNCIL

WINTER SESSION

The winter session of the General Medical Council ended on November 28 after a four-days meeting. Mr. H. L. EASON was re-elected President for a further term of two years. The business before the Council was almost entirely concerned with disciplinary cases, of which there were twenty on the programme.

REPORTS OF COMMITTEES

The committee reports presented during the recent session of the General Medical Council were only on routine matters. Mr. Ritchie, who presented the report of the Public Health Committee, said that the committee had been considering the comments made by licensing bodies on the general report of the Council on the visitation (1938-9) of the examinations for the D.P.H. The Universities of Manchester and St. Andrews, the London School of Hygiene and Tropical Medicine, and the Scottish Branch of the Society of Medical Officers of Health had not yet sent in their comments, but the committee hoped to receive them as soon as possible.

Dr. Campbell, who presented the report of the Pharmacopoeia Committee, said that the British Pharmacopoeia Commission had carefully considered the modification of certain pharmacopoeial formulae with a view to effecting economy in the use of alcohol. Experiments on this subject were proceeding, and it was probable that another Addendum—the fifth—to the *British Pharmacopoeia*, 1932, would be necessary in order to give effect to the recommendations. The Commission had continued its policy of giving names to chemical substances now being made in this country, and he hoped that manufacturers here who obtained the patent rights to make these substances would use the names suggested, so that the same substance would not be known by half a dozen different names.

DISCIPLINARY PROCEEDINGS

Restorations to Register

After consideration *in camera* it was announced that the following names had been restored to the *Medical Register* after penal erasure: John William Paterson Collyer, William Joseph Doody, William Aloysius Kennedy, Francis Stedman Poole, and James Pearson Thierens.

Cases in which Judgment had been Postponed

The Council first dealt with certain cases in which the facts alleged against the practitioner had been proved at a previous session, but judgment had been postponed. In the case of Reuben Denny, against whom a conviction of driving a motor car while under the influence of drink and another of being drunk and incapable had been proved, a medical certificate was put in stating that Dr. Denny was suffering from nervous breakdown, and the Council postponed the case until next session. In the case of Christopher Bastible, against whom a conviction of being in charge of a motor car while under the influence of drink had been proved, a letter was received from the respondent stating that he would prefer not to ask for testimonials in a small country town and run the risk of injuring his reputation, but he enclosed a satisfactory testimonial from another doctor who was employing him. The Council again postponed judgment until November next. In the case of Henry McNeill, against whom the charge had been proved that on one occasion he was so far under the influence of drink that he was incapable of properly carrying out his professional

duties, a number of testimonials were put in. It was also stated that Dr. McNeill at the end of last year had his house and surgery completely destroyed by enemy action. The Council decided not to proceed to erasure, and dismissed the case.

Alleged Misleading Certification

The first of several cases which had to do with certificates was that of Albert Alexander Gunn, registered as of Pownall Park, Wilmslow, Cheshire, who was summoned on the charge that on March 5 last he gave certificates, notifications, reports, or documents of similar nature in his professional capacity for subsequent use for administrative purposes under the National Service Acts in the cases of six youths, inmates of an institution, when in fact he had not seen or examined these persons on the date mentioned or at all.

Dr. Gunn was represented by Mr. A. Pereira, counsel.

The Council's Solicitor (Mr. Winterbotham) said that the six persons mentioned were youths of the 19-year-old class, inmates of a mental home near Ludlow, who were summoned for examination by the Hereford Medical Board. Certificates with regard to them, given by Dr. Gunn, then of Ludlow, were handed to the chairman of the board, Dr. Bulman, together with a typewritten sheet giving a short account of each of the boys to be examined. On questioning the boys it appeared that none of them (with one doubtful exception) had ever been examined or attended professionally by Dr. Gunn, and it seemed that the lay person in charge of the home, a Mr. G. H. Lyward, had furnished the details of the six cases in the form of a typewritten sheet which had been copied verbatim by Dr. Gunn in the form of medical certificates. It was added, however, that apart from this irregularity of certification the cases appeared to be quite genuine, for each candidate, following upon his examination by the board, had been examined by the consultant psychiatrist and graded IV as a result. Dr. Gunn, in a letter to the Council, stated that he was very ill at the time and had failed to appreciate the purpose for which the documents were desired. The boys belonged to a school in Kent which was evacuated to Shropshire, and the doctor in Kent, who had been doing any necessary service for the school, gave a letter of introduction to the doctor in Ludlow whose practice was being looked after by Dr. Gunn in his absence. It was contended by Dr. Gunn that the documents were not certificates, but even so the Council's warning notice referred to "certificates, notifications, reports, or documents of a similar nature."

Mr. Pereira, for Dr. Gunn, said that the doctor had understood from the schoolmaster, Mr. Lyward, that most of these cases had been sent to the school by well-known psychiatrists. He thought he would first look at the case papers, which he did, and then would see the boys, and in fact he did see one of them. Then he was taken ill, and while ill he received an urgent letter from Mr. Lyward saying that the boys were being called up for a military board and asking him to give a résumé of their medical history and condition for the use of the board, and he did so from the notes sent to him. He fully appreciated now that he should not have done so, but he did not "certify" anything.

The Council found the facts proved, but in view of the explanation Dr. Gunn had given they did not see fit to instruct the Registrar to erase his name.

A Question of School Certificates

The Council next considered the case of Israel David Black, registered as of 649, Leeds Road, Bradford, who appeared on the charge of having issued three certificates in February and March last to the effect that Ronald Hindle, a boy aged 12, was suffering from chill—or on one of the dates from influenza ebullency—and was unable to attend school, whereas in fact Dr. Black had not examined the boy on any date mentioned or at all, and that the boy was quite able to attend school on each occasion.

Mr. A. Pereira, on behalf of the London and Counties Medical Protection Society, defended Dr. Black.

Mr. Winterbotham, the Council's Solicitor, said that in Bradford compassionate school leave was given if circumstances arose in the home which made it necessary for the mother to have the temporary help of an older child. In this case, owing

to the illness of a married daughter, two grandchildren were added to the care of Mrs. Hindle, who sent Ronald to Dr. Riley, then Dr. Black's assistant, and he certified that the daughter was ill and that it would be a help if the boy were excused school. Later on another certificate was required, and the boy saw Dr. Black, who gave him the first of the certificates mentioned in the charge, stating that the boy was suffering from a chill, although at the time he was perfectly well. This certificate was accepted and endorsed by the school medical officer, as was a second certificate, but when a third was issued the senior school medical officer got in touch with Dr. Black, who agreed that the boy was fit for school.

Evidence was given by Mrs. Hindle to the effect that on all these occasions the boy was perfectly well and that Dr. Black never examined him. Dr. Black, who was her married daughter's doctor, attended at the house to treat her grandchild; he never examined Ronald. A bill for 14s. for Dr. Black's services had been presented; she herself did not see the bill until a week ago. Ronald Hindle also testified that Dr. Black did not examine him.

Dr. Black, in evidence, said that he was an alderman of the city of Bradford. This boy and his mother had not been patients of his. He was called to see the granddaughter on February 7, and Mrs. Hindle then complained of the condition of the house, which she said was damp. He inspected the house and promised to report it. Mrs. Hindle said that the house gave all the family colds and that Ronald had been coughing. He opened Ronald's shirt, listened to his chest, and took his temperature. He found signs of bronchial catarrh, and in view of his condition and of the severe weather at the time he thought it would be better if he stayed away from school. He also dispensed some medicine for him. He continued to visit the grandchild at the house, and on the second occasion Mrs. Hindle gave him a form which had been left by the school attendance officer with regard to Ronald, and this he filled in after again examining the boy. On the third occasion similarly he examined and treated him and gave a certificate, but a few days later he refused a request for a further certificate, having heard that in the meanwhile the boy was employed delivering newspapers. His accounts were rendered either quarterly or half-yearly, and particulars were given to his collector. The account for 14s. which Mrs. Hindle said that she had seen only on the previous Saturday had in fact been rendered some weeks previously, and half of it had been paid in small instalments by Mrs. Hindle's daughter.

In reply to questions by Dr. Bone and other members of the Council Dr. Black said that he made up his account book from his visiting lists, which he destroyed after such entry. He admitted that he had thus destroyed any direct evidence of his attendance on Ronald Hindle, although he knew that an inquiry had been made by an education subcommittee in Bradford at which his statement that he had examined this boy had been challenged; but he said that he did not destroy the lists until about a month after the inquiry, when, having heard no more, he considered the incident closed. He had had no idea at that time that the matter would come before the General Medical Council.

The Council, after deliberation *in camera*, found that the facts alleged against Dr. Black had not been proved to their satisfaction, and the case was dismissed.

Alleged Agreement to Break Rules in a Maternity Ward, Falsification of Temperature Records, and Failure to Notify Pyrexia.

The Council considered charges against William Blackwood, D.S.O., registered as of Camborne, and Harry Lee Shimmin, registered as of Redruth, of wrongfully agreeing together to commit a breach of the rules made by the county medical officer of health for Cornwall for the management of the maternity ward provided under a scheme of the county council at the Camborne-Redruth Miners' and General Hospital, of which they were medical officers, and of falsifying or causing to be falsified the records of temperatures of patients in the wards for whom they were responsible, and failing to notify the county medical officer of health as required by those rules. It was further charged against Dr. Shimmin that in a specified case he had failed to notify the medical officer of health for the district as required by the Puerperal Pyrexia Regulations, 1939.

Mr. G. M. Howard, counsel, instructed by Waterhouse and Co., solicitors, in outlining the facts of the case, drew attention to the Puerperal Pyrexia Regulations which came into operation on April 1, 1939, in particular to Section 2 (1), which specified the meaning of the term "puerperal pyrexia." He also referred to rules made by Dr. Curnow, as county medical officer of health for Cornwall, for the maternity ward of this hospital. One of these rules read:

"Any rise of temperature in a patient, however slight, may be a warning sign of impending puerperal sepsis. Therefore, a rise of temperature to 99.4° with proportionate quickening of the pulse rate or any other symptoms or signs suggestive of sepsis is sufficient to require the removal of the patient to an isolation ward. . . . Such a case must be regarded from the beginning as infectious until the contrary is known. . . . If the pyrexia recurs to 99.4° for three successive days or reaches 100.4° and is maintained or recurs within 24 hours then the case is definitely infectious and must be removed as soon as possible to the Tuckingmill Clinic or to one of the Plymouth hospitals."

A further rule stated:

"If any of the incidents [including the significant rise of temperature] specified above occur the county medical officer of health must be notified at once by telephone and the appropriate procedure immediately undertaken."

Not only was the attention of these doctors called to these rules, but they were consulted with regard to them and apparently expressed their entire agreement. In a letter dated September 26, 1939, Dr. Blackwood wrote to Dr. Curnow with regard to two cases to which his attention had been drawn, and said *inter alia*: "I fully realize the necessity of carrying out the regulations laid down by you." The sister in charge of the ward from September, 1939, to March, 1941, was a Miss Commerford, who would say that the doctors agreed together that they would not follow Dr. Curnow's rules in the respect that if a patient had a temperature of 99.4° F. which recurred or reached 100.4° F., they would wait to see what happened, and if nothing further happened then the temperature chart could afterwards be falsified so as to make it appear that the patients had not come within these rules. This evidence would be supported by two other sisters. Dr. Blackwood was charged with falsifying temperature records in two cases. Against Dr. Shimmin there was no charge respecting the temperature chart of any particular patient, but that he failed to notify the district and the county M.O.H.

Dr. R. N. Curnow, M.O.H., Cornwall, testified that in drawing up the rules for the maternity ward he consulted Dr. Blackwood, and later had a conference with the medical staff at which the rules were discussed and agreed. A nurse took the temperatures in the ward and entered them in a book, and a sister afterwards made up the chart from the book. On Dr. Blackwood's charts there was no necessity for notification, but on Dr. Shimmin's charts relating to a Mrs. Cornish, who died in the ward, an inquiry took place, at which Sister Davies made statements in the presence of the two doctors, saying that she had been engaged for some time, with their knowledge, in the falsification of temperature charts. Dr. Blackwood pressed her to say that it was only temperatures under 100° F. which had been affected on two or three occasions, but she would only reply that it might have been so; she could not swear to it. Sister Love also said that the charts had been faked over a considerable period.

Cross-examined by Mr. A. Pereira, counsel, instructed by Messrs. Le Brasseur and Oakley on behalf of the London and Counties Medical Protection Society, who defended, Dr. Curnow agreed that when Drs. Blackwood and Shimmin arrived at the hospital inquiry they had no idea that any suggestion was going to be made against them. Sister Davies said at the inquiry that she had carried on a system which had been in operation for a long time, and was doing what she had been instructed to do by Sister Commerford. She agreed that she never said that either Dr. Blackwood or Dr. Shimmin had told her to alter any chart; she said that it was done with their knowledge, not on their instructions. Another sister at the inquiry had corroborated that the temperature charts were falsified; the system was, she said, that the doctors were to be consulted before the second high temperature was recorded.

It was suggested to Dr. Curnow by counsel that there was not sufficient staff for the number of cases in this busy ward, and that if infectious cases occurred one nurse (out of three) had to be taken off the ward to look after the isolated case.

Miss Margaret Commerford gave evidence that at the time she became sister-in-charge she had a discussion with Dr. Blackwood regarding temperatures. She was told that if patients' temperatures went up she was to notify them, but second high temperatures were not to be charted until the doctors had seen the patient. Temperatures were entered on the chart from the temperature book the following morning by the junior sister. In cross-examination it was put to the witness that Dr. Blackwood had never instructed her at any time to mark any lower temperature than the correct one, but she said that he did so, and that Dr. Shimmin also was present at the conversation. She said that if a patient had a temperature of 99.4° F. they waited until the next morning, and then, if the temperature was still up, the patient was isolated; if the temperature was then down she saw Dr. Blackwood and took his

instructions. Dr. Curnow's rule was that even if the patient had 99.4° F. on one occasion she was to be isolated at once.

If there was a temperature of 100.4° F. in the evening, what instructions had you from Dr. Blackwood?—Not to do anything until the patient was seen next day by Dr. Blackwood or Dr. Shimmin.

Was the temperature charted?—Yes, it was.

So that night there would appear on the chart 100.4° F.?—Yes.

The doctor would come next morning and this would be reported to him. Then what were his instructions?—That if the patient still had the temperature we were to take swabs and isolate her, and if the temperature was up in the evening she would have to be sent to Truro.

If the temperature was normal or below normal in the morning it would be all right.

Sister Esther Davies, who was employed at the hospital until June, 1941, said that if the temperature was 99.4° F. in the evening she did not chart it. If it went down in the morning the temperature was then charted. If it did not go down to normal or below, the doctor was notified. She received instructions that she might have to put wrong temperatures on the chart, but she never actually did so. While she was there as junior sister she knew of one case in which wrong temperatures were put on the chart by Sister Commerford, and of two other cases in which wrong entries were made by Sister Love: she herself had told Sister Love to make them, as instructed by Sister Commerford. The temperature book, in which the original entries had been made in pencil, was altered so as to coincide with the charts, and she agreed that there would be no evidence as to the real temperatures of the patients concerned.

Sister Ena Love, who had been junior sister in this maternity ward, was asked whether the correct temperature was always put upon the charts, and replied "No." Asked in what circumstances a wrong temperature would be put upon a chart, she said that if 99.4° F. occurred twice, and there was nothing else in the patient to suggest anything wrong, the second temperature was not charted: something lower was entered.

When the wrong temperature was put on the chart, who decided the actual temperature to be recorded?—I did.

Why did you do it?—I knew it was wrong in principle, but no harm was being done.

How did you know no harm was being done?—Because the patient was perfectly well.

Mr. Pereira at this point said that so far as the charge of falsifying documents was concerned no evidence had been given by the sisters sufficient to place on him the onus of calling rebutting evidence. Any court would stop the case at this point. The last two witnesses had offered no evidence that the doctors had called on them to falsify, and the first witness had contradicted herself and had said that there was no case she knew of being improperly charted. With regard to failure to notify in accordance with the rules of the hospital, that was a matter before the two doctors and the hospital, and ought not to come before the Council. These doctors were under no penalty for failing to comply with the rules, and he suggested that Dr. Curnow had no authority in this voluntary hospital to impose the rules. The doctors had agreed to comply with the rules, but a breach would render them liable only to civil action. As for the failure of Dr. Shimmin to notify under the Puerperal Pyrexia Regulations, that might be an offence before another court, and then, if a conviction were recorded, might come on to the Council, but it was not a case to be brought before the Council as infamous conduct in a professional respect.

Mr. Howard agreed that as to the first charge there was the evidence of only one witness, Sister Commerford, and the Council might think it not safe or right on the uncorroborated evidence of one witness—a witness, moreover, who was implicated in what was done, to say that this matter was proved beyond reasonable doubt, in which case he would not press the charge. But he suggested that on the further charge against Dr. Shimmin he ought to have notified the case of Mrs. Cornish, even though the only evidence was that of one of the sisters—Sister Love—who was again uncorroborated and implicated.

The Council deliberated *in camera* and found that the facts alleged against Dr. Blackwood had not been proved to its satisfaction. Dr. Blackwood was therefore dismissed from the case. The Council also found that the facts alleged against Dr. Shimmin in respect of falsification of records had not been proved, but desired to hear the defence with regard to failure to notify.

Dr. Shimmin then went to the witness chair, and was examined with regard to the case mentioned. He agreed that, looking at the case now, he ought to have notified it. It was a case

which, by reason of the high temperature, came within the statutory rules and orders, and also, of course, within the rules laid down by Dr. Curnow. He told Dr. Curnow by telephone about the case, but that, of course, did not cover the requirement to comply with the Puerperal Pyrexia Regulations. He thought he had done his duty in notifying Dr. Curnow on his instructions.

The Council again deliberated *in camera*, after which the President addressed Dr. Shimmin as follows:

"The facts alleged against you in paragraphs 3 and 4 of the charge [failure to notify] have been proved to the satisfaction of the Council. The seriousness of the facts in the case of Mrs. Cornish is that you infringed regulations made in the public interest for the protection of women after childbirth, and that in the case of Mrs. Wame and Mrs. Waters you similarly infringed the regulations. Further, you failed in the case of Mrs. Cornish to honour the undertaking you gave to the medical officer of health to acquiesce in the rules drawn up by him, as you must have known, for the sole purpose of preventing maternal mortality and morbidity. The Council takes a grave view of these successive derelictions of duty, both under the statute and in relation to a colleague. They trust that these proceedings will cause you to be more scrupulous in future in the discharge of those obligations. Taking that into account, they have decided not to direct the Registrar to erase your name from the Medical Register."

(To be concluded)

Correspondence

District Medical Officers' Duties

SIR.—I am glad to see, from the *Supplement* of November 15 (p. 92), that district medical officers are waking up to the impositions that are being put upon them. The Old Age Pensions and Widows Act, 1940, laid down that those pensioners who are not entitled to medical attendance under the Insurance Act should have free medical relief provided for them. The onus of arranging this naturally passed to the Ministry of Health, who by the Public Assistance Order (No. 2), 1940, quietly "passed the buck" to the district medical officers.

This Order is the authority under which the inspectors of the Assistance Board, which latter assesses supplementary pensions, inform pensioners that they are entitled to free medical attendance, and that they should apply to the relieving officer of their local public assistance authority, who has now no alternative but to issue a "permanent ticket." In this way the law of this country instituted a new medical service and the Minister of Health quietly passed on the work to the district medical officers without any reference to their contracts and without any consideration of the extra work or of the increased expenditure in providing drugs and in travelling.

Is it not about time that medical representation in Parliament was put upon a firmer basis so that matters which affect the welfare of the profession may come under the consideration of those most intimately concerned with them before they become law?—I am, etc.,

Sudbury, Suffolk, Nov. 19.

J. B. ALEXANDER.

* The effect of the amendment of Article 23 of the Public Assistance Order, 1930, is that a public assistance authority is empowered, on application, to include in the permanent medical relief list the names of supplementary old age pensioners and those of their dependants who are aged, infirm, etc., and whose needs have been taken into account in calculating the supplementary pensions. It would appear that once a pensioner or his dependant is included in the list or receives medical relief during any particular half-year he is automatically included in the succeeding half-years so long as the supplementary pension continues to be paid. Representations have been made by the B.M.A. to the Ministry of Health on the issue of increased work thrown on district medical officers, with particular reference to their remuneration.—ED., *B.M.J.*

Bridging the Gap

SIR.—The pamphlet just issued by the Secretary of the British Medical Association appears to be in the nature of an apology. None the less it is a valuable means of bridging the gap between the Council and general practitioners and is, therefore, to be

welcomed. It brings about a liaison which was shown by the special conference of representatives to be badly needed. It might have been better not to vent antagonisms to kindred organizations, but this is a question of policy and taste. I would make a plea for the sake of the welfare of the nation and the medical profession: co-operation with other medical bodies should be brought about instead of endeavouring to shut the door on those who can help in the great work. At a recent general meeting in this Division I stressed the importance of giving full support to the efforts of the B.M.A. to cope with current and post-war problems, but it would be better to have unity than dissension. With all respect, I would ask if the Council of the Association is not too conservative in its outlook:—I am, etc.,

L. S. WOOLF,
Chairman, Hendon Division, B.M.A.

Nov. 25.

PROTECTION OF CARS AGAINST FROST

The Minister of Transport wishes to call the attention of all users of motor vehicles to the importance of taking the utmost precautions against the danger of damage to their vehicles through freezing. If a vehicle has to stand in the open for any length of time the best antifreeze device is an empty water system. On some motor vehicles two taps are provided for draining, one for the radiator and the other for the cylinder block. When the cooling system is being emptied both taps should, of course, be opened.

There is very little "antifreeze" available in this country for the coming winter, and therefore anyone owning or operating a motor vehicle should, whenever possible, adopt some alternative method of protection. This is particularly important in view of the fact that certain spare parts for motor cars may be in short supply; frost damage may, therefore, immobilize a vehicle whose continued operation is vital for the war effort. The small existing supplies of "antifreeze" available for civilian road transport will be allocated by the Regional Transport Commissioners of the Ministry of War Transport, and any operator of vehicles engaged on essential national work who cannot protect his vehicle in any other way should therefore make application to the appropriate Commissioner, giving full particulars of his demands.

The B.M.A. has represented to the Ministry of War Transport the vitally important nature of the work being performed by medical practitioners, often in circumstances of peculiar difficulty, and the extreme inconvenience of an empty water system, especially when urgent night calls are received. The Ministry does not deny that doctors must be included among those car users who may be regarded as having special claims in this matter, but unfortunately the supplies of "antifreeze" available are such as to meet only a small proportion of the proved demand. Therefore, while doctors are not debarred from making application to the Regional Transport Commissioners, it is to be expected that their applications will be successful only rarely and in quite exceptional circumstances. Car users are warned that certain mixtures purporting to give protection against frost are not fully effective and may even do actual damage, and they should satisfy themselves on these points before relying upon them.

MILK AND EGG CERTIFICATES

General practitioners will have been harassed or overwhelmed during the past two or three weeks by applications from patients for certificates for priority supplies of milk and eggs. In the *Supplement* of October 4 the Council of the B.M.A. expressed appreciation of the way in which the Ministry of Food had met its criticisms of the schedule of conditions for priority milk supplies. The circumstances of the issue of the schedule by the Ministry, however, have caused endless trouble to the profession, and the Association considers it to be its duty to disclaim all responsibility for the deplorable muddle.

First, the schedule of conditions was issued by the Ministry itself to medical practitioners, but many doctors did not receive a copy. Those who inquired at their local Food Offices were incorrectly informed that the British Medical Association was

responsible for the issue, and further delay occurred while applications for the schedule were redirected by the Association to the Ministry. Secondly, the schedule was issued as a confidential document. This was doubtless done with the best intentions, but the result was that doctors' surgeries were filled with patients who thought they might be entitled to extra milk for any kind of illness. The normal work of practices was seriously hampered, and friction between doctor and patient frequently followed refusal of a certificate. Thirdly, some Food Offices, regardless of the confidential nature of the schedule, issued a circular to the public purporting to give the conditions for priority supplies, but as the circulars were incorrect and misleading they only made matters worse. The Association has accordingly urged the Ministry to issue a public announcement through the Press and the B.B.C. stating clearly the conditions for which alone priority certificates may be given.

The arrangements for priority supplies of eggs came into force on November 17, but although local Food Offices sent medical practitioners batches of certificate forms, the schedule of conditions for which the certificates might be given was not issued by the Ministry until a fortnight later. In the meantime Food Offices were informing practitioners that the British Medical Association was responsible for the delay, and the Association had again to redirect inquiries to the Ministry.

The Association has now sent a letter to the Ministry strongly protesting against the unnecessary difficulties placed by both its central and local offices in the way of medical practitioners, who are already sufficiently inconvenienced by the numerous claims for wartime certificates.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetric and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m., Post-mortem Demonstrations. *Mon.*, Course on War Surgery of the Extremities commences. *Tues.*, 10 a.m., Paediatric Clinic, Dr. Lightwood; 11 a.m., Gynaecological Clinic, Mr. Green-Armytage. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical). *Thurs.*, 2 p.m., Dermatological Clinic, Dr. R. T. Brain. *Fri.*, 12.15 p.m., Clinico-pathological Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. Green-Armytage.

ROYAL SOCIETY OF MEDICINE

Section of Comparative Medicine.—*Wed.*, 2.15 p.m. Discussion: Control of Diseases in Cattle inimical to Man: II, Tuberculosis. Openers, Prof. T. Dalling and Dr. S. Roodhouse Gloyne.

Section of Neurology.—*Thurs.*, 2.30 p.m. Discussion: Rehabilitation after Injuries to the Central Nervous System. Openers, Prof. Geoffrey Jefferson, Prof. Hugh Cairns, Dr. W. Russell Brain, and Dr. Ludwig Guttmann.

ROYAL INSTITUTION, 21, Albemarle Street, W.—*Tues.*, 2.30 p.m., Prof. J. C. Drummond: Recent Advances in the Science of Nutrition and their Significance in Wartime.

B.M.A.: Branch and Division Meetings to be Held

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.—At St. Mary Abbots Hospital, Marloes Road, Kensington, W., *Tuesday*, December 16, 2.30 p.m. Clinical meeting.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTH

VAUGHAN-JONES.—To Maureen (née Cooke), wife of Surgeon Lieutenant R. Vaughan-Jones, Royal Navy, Royal Naval Air Station, Trinidad, B.W.I., on November 28, 1941, a daughter, "Angela Maureen."

DEATH

MONKS.—On November 30, 1941, at "Fair Lawn," Bradford Street, Bolton, Alderman Ernest Monks, M.B., Ch.B., J.P., dearly loved husband of Eliz. H. Monks, aged 70 years. Interred at St. James's Church, Brightmet, Bolton.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 20 1941

BRITISH MEDICAL ASSOCIATION

PROCEEDINGS OF COUNCIL

A meeting of the Council of the Association was held at the House in London on December 10, with Mr. H. S. SOUTTAR in the chair.

The deaths were announced of two former members of Council, Dr. J. C. Loughridge of Belfast and Sir Alfred James Rice-Oxley of Kensington, and resolutions of condolence with the families were passed. Representatives of the Association on outside bodies were reappointed, in some cases with substitutes in the event of the representative being unable to attend. The Journal Board was reappointed in the persons of Prof. R. J. A. Berry, Colonel R. G. Gordon, Dr. J. C. Matthews, Dr. H. Robinson, and Major R. Scott Stevenson. The Treasurer of the Association, in that capacity, was also made a member of the Board.

The Chairman reported that he had led a deputation to the Ministry of Labour in connexion with a number of important problems arising on the report of the Industrial Health Committee—a report which he considered to be one of the most valuable documents ever issued by the Association. A long discussion took place with the Minister and heads of Departments, and he believed that it would bear very good fruit.

It was reported that the income of the Sir Charles Hastings Fund would no longer be subject to income tax. The Chairman said that the Sir Charles Hastings Fund was the one charitable fund which the Association itself controlled, it was used exclusively for the assistance of medical men, and it had always been a sore point that income tax had to be paid upon it.

On the reports of the Executive and the Office Committees, various action which had been taken with regard to the staff and the building was endorsed by the Council. The action initiated on the decisions of the recent Conference of Representatives of Home Divisions was also approved. On the matter of discussion groups a memorandum on the main subjects which had already been before the various committees of the Medical Planning Commission was being issued to Divisional secretaries, with a suggestion that each Division should organize a Study Group to consider this memorandum and to report its findings.

The National Eye Service

Mr. Bishop Harman reported the conclusions of the meeting of the Ophthalmic Group Committee regarding the fee for ophthalmic medical examination, as fully set out in the *Supplement* of November 29. These laid down the following conditions as applying in the National Eye Service:

- (1) Insured persons whose incomes do not exceed £250 per annum, and their dependants, will be accepted for treatment at a fee of 10s. 6d. each.
- (2) Non-insured persons, other than dependants mentioned in (1) above, whose incomes do not exceed £250 per annum may be considered as applicants for treatment at a fee of 10s. 6d. each.
- (3) For all other insured persons (including all manual workers and voluntary contributors with an income exceeding £250) the fee for an ophthalmic medical examination shall be £1 1s. each.
- (4) The fee for all persons who do not fall within the above categories shall be at the discretion of the ophthalmic medical practitioner.

These proposals had been submitted to all practitioners doing National Eye Service work, and of those replying only just over 3% had expressed disagreement. The committee itself was unanimous.

Dr. S. Wand moved the omission of No. 3 of the proposals. He deprecated a sliding scale, which would introduce many difficulties. On the previous day the Public Medical Services Conference had decided that its services should be available only to those with £5 a week or less. Moreover, the profession as a whole had expressed its dissatisfaction at the new inclusion in national health insurance of non-manual workers earning from £250 to £420 a year. Dr. Roper seconded this amendment.

Mr. Bishop Harman hoped that the Council would not agree to omit this paragraph. All the proposals applied only "until further notice," and if they were found to work badly they could be looked into again. This service was not on parallel lines with the others; it was for an ophthalmic examination, not for continued treatment.

Dr. F. Gray said that while the Public Medical Services Conference had agreed that the income limit should be £5 a week, it had also declared that any Service which desired to bring persons of higher income into its contract arrangements might do so by means of an extension, and the equivalent of that in the National Eye Service was set out in paragraph (3).

The amendment to omit paragraph (3) was not accepted, and the four conditions as they stood were endorsed by the Council.

Mr. Bishop Harman said that the number of cases dealt with by the National Eye Service during the past year showed a substantial increase, mainly owing to the examination of Army personnel. The arrangement with the War Office, however, had now been replaced to a large extent by the establishment of War Office refraction centres. The civilian cases showed a steady improvement for the corresponding period of 1940, and the civilian returns for October were the highest received during the twelve years' history of the Service. Unfortunately a number of centres had to be closed owing to the calling up of skilled dispensing opticians.

Increase in Fees in Contract Practice

In presenting for the first time as chairman the report of the General Practice Committee, Dr. Wand paid a graceful tribute to his predecessor, Dr. J. W. Bone, who had rendered exceptional service as chairman of the Medico-Political and General Practice Committees for fifteen years. The principal matter in the report was the recommendation that the 20% increase in fees for general practice should apply not only to private fees but also to colliery and other contract practice arrangements: that a similar increase should be sought, subject to the approval of the practitioners concerned, in the fees of police surgeons: that representations should be made in the proper quarter for an increase of not less than 20% in the fees for medical examination for life assurance: and that similar representations be made to the National Deposit Friendly Society.

Dr. J. B. Miller expressed some misgiving about the reference to colliery practice arrangements. Negotiations were proceeding in Scotland for an increase in medical fees in the mining industry, which had undergone no change for more than twenty years. During those years a great increase of work had devolved upon the colliery surgeon: treatment was more expensive on account of the more costly drugs which had to be provided by the doctor who supplied his own medicines; and, again, miners now lived at a much greater distance from their work than was formerly the case, involving longer journeys for the doctor in paying visits. An increase merely of 20% could hardly be defended in mining practice: it should be much more like 50% or 100%. He hoped the reference to colliery practice would be left out of the recommendations.

Dr. Gray pointed out that the phrase generally used was "at least 20%," and that this was a purely wartime increase; it must not be held to govern the situation where, as in colliery practice, an endeavour was made to get an all-round increase in the basic fee. Dr. Wand also said that Dr. Miller's figures related to fees which were inadequate in the pre-war period and which in fact had not been altered since 1919.

It was agreed to leave out the reference to colliery practice and also to put "wartime" in front of the expression "20% increase."

Salaries of District Medical Officers

One question in this connexion had been left for the consideration of the Public Health Committee, but Prof. Picken, the chairman of that committee, said that he was prepared to take the responsibility of giving assent. The Council thereupon agreed to advise Divisions or Branches to endeavour to secure, first, that as a wartime measure the salaries of district medical officers be readjusted in view of the burden of additional work, the increase in practice expenses, and the inclusion in the permanent medical relief list of supplementary old age pensioners who are entitled to the services of the district medical officer; and, secondly, a wartime percentage increase in the fees of public vaccinators.

Pensions Medical Boards

Dr. Wand said that after discussion with the Ministry of Pensions the following scale had been agreed as sessional payments for members of pensions medical boards:

No. of Weekly Sessions	Specialists	Chairmen	Members
	£ s. d.	£ s. d.	£ s. d.
1	3 2 6	2 10 0	2 0 0
2	2 12 6	2 2 6	1 15 0
3	2 2 6	1 15 0	1 10 0

It was also reported that as a result of representations to the Board of Trade the Board had agreed that drugs and medicines, where supplied by a doctor who conducts his own dispensary, are insurable under the business scheme created by Part II of the War Damage Act, 1941, instead of under the Commodities Scheme of the War Risks Insurance Act, 1939. Under the latter scheme, which the Board of Trade at first was of opinion held good in such a case, the doctor would have been required to take stock and work out premiums monthly. The opinion of counsel, which was sought by the Association, was that dispensing practitioners are not "carrying on business" for the purpose of the War Damage Act, and therefore their drugs and medicines are insurable under the Business Scheme.

Insurance Acts Committee

Dr. E. A. Gregg, chairman of the Insurance Acts Committee, presented a report covering most of the matters which were reported in the *Supplement* of December 6, following the meeting of that committee. He said that in spite of somewhat stormy weather the committee had succeeded in riding the seas, and in the recent election of the 26 direct representatives, when the members of the profession engaged in insurance practice had the opportunity, if they so desired, of making drastic changes in personnel, only five such changes were made, and one of those was occasioned by the death of a former member and another by the fact that the sitting member did not seek re-election.

The committee felt that it had now reached a position at which it was possible to make some further move with regard to remuneration. The possibilities of making a claim for an increase on the ground of increased cost of living were being investigated. There was a substantial and growing feeling that the economic position of insurance practitioners justified the granting of a cost-of-living bonus.

It was also proposed to go to the Ministry with a view to seeking firmer assurances that the committee would be consulted before any matter affecting the terms and conditions of service of insurance practitioners was announced. This arose out of the failure of the Government to undertake such consultation before announcing legislation which brought in the new higher-income group of insured persons.

Hospital Policy

Dr. Peter Macdonald brought forward the report of the Hospitals Committee, which embodied the committee's consideration of the resolutions of the Annual Representative Meeting, 1939, on the revised Hospital Policy.

On the question of out-patient departments Prof. Picken mentioned the acuteness of this problem in wartime. Those concerned with the work of the Central Medical War Committee were faced with the task of finding men for the Services, a large number of whom must come from hospitals, and part of the plea of the hospitals for the retention of their staffs was based on the huge growth of the out-patient departments. It was unfortunate at any time, and at the present time particularly unfortunate, that there should be such an influx of out-patients. Could the Association do anything to stay this growth? The departments were to a large extent doing work which the general practitioner was quite prepared and competent to do. It was true that the teaching hospitals were in a special position, but this growth of out-patients went far beyond them.

Dr. Macdonald said that he was in entire agreement. The difficulty was to cut down the departments in wartime, when there were so many persons who were not able to get the attention they wanted—or thought they wanted—from their ordinary practitioners.

The Council dealt with some other routine business and rose after a sitting of three and a half hours.

MEDICAL PARTNERSHIPS IN WARTIME

[FROM A CORRESPONDENT]

After two years of war lawyers and others interested in medical partnerships have had an opportunity of studying the effect of war conditions upon partnership affairs. By far the most difficult problem is that of the partner absent on war service, and it is proposed to consider only this aspect here.

There were originally, and still are, two main methods of dealing with a situation which bristles with difficulties. The first, which was referred to in these columns on November 11, 1939 (p. 219), has been found to be generally less workable than the second. Shortly the essential difference between the two methods is that in the first the absent partner retains his pay and allowances, while in the second these items (except perhaps certain allowances) are brought into the firm as partnership receipts.

Now it has seemed to those called upon to advise partners—whether the latter are remaining at work or are away serving in the Forces—that any scheme should secure: (a) that so far as possible the partners are left relatively in the same position financially as formerly; (b) that the existing Articles should be altered as little as possible; and (c) that special circumstances in each case should be considered and dealt with.

Where a partner absent on war service retains his pay and allowances, it is, of course, possible by adjustments of his share and of the expenses to carry out the intentions of (a) and (c). But the ordinary provisions of partnership Articles are entirely upset, and adjustments of shares are not too easy to calculate. In fact, under such an arrangement there is very little in the Articles which remains effective, and this, in itself, has a bad effect in cases—only too frequent—in which difficulties and disputes have arisen regarding the absence of one or more partners. If, however, it has been decided that in a particular case pay and allowances shall be retained by the absent partner, the main question to settle is what share of profits shall be paid to him. Fifty per cent. of the share due under the partnership agreement was at one time considered reasonable, based upon the B.M.A. Scheme for the Protection of Practices of Absentee General Practitioners.

Any fixed proportion to apply to cases generally would appear to be wrong, as consideration has to be given to the amount of pay and allowances, the return from the share, and any other relevant matters.

Four Fundamental Principles

Where, however, an absent partner brings into the firm his pay and allowances the partnership Articles are, so far as possible, adhered to, and this method is now most usually and, it is suggested, properly advised. The chief points are as follows:

1.—The absent partner brings into the firm the whole of his pay and family allowances. He usually, but not invariably, retains other allowances, which are in the nature of reimburse-

ments for actual out-of-pocket expenses, and any gratuity, disability pension, and prize money.

2.—The absent partner retains his full share of partnership net profits.

3.—Expenses are adjusted as seems fair and reasonable. For instance, the absent partner, as a rule, has no car expenses, whereas the remaining partner (or partners) is usually put to greater expense in this respect. Again, extra surgery expenses may be placed upon the remaining partner or partners, including cost of heating and lighting, etc. Each item of expense should be considered and settled according to the particular circumstances of the case.

4.—A locumtenent or assistant may be required directly owing to the absence of a partner on war service or indirectly when a remaining partner is obliged to be away or to have help. Such assistance, therefore, as may become necessary should be provided at the partnership expense.

These, it is suggested, should be treated as basic principles, and if they are followed it should be possible for a reasonable arrangement to be arrived at in every case. It must be borne in mind, however, that even if the general scheme is adopted there has to be agreement over details, and such agreement is impossible without good will and consideration on both sides. In this war it is not sufficient for an absent partner to say, "I am serving my country," and let it go at that. The "stay-at-home" doctor not only has to carry on the whole work of the practice but often has to run at least equal risks of death or bodily hurt as a serving partner.

In conclusion it should be pointed out that whatever the basic scheme adopted, partners and their advisers should give some thought to the problems which would arise from retirement or through death, particularly if the remaining or surviving partner is under an obligation to purchase the retiring or deceased partner's share at a fixed price, which may in these times be quite unreasonable.

WEST HAM PRACTITIONERS' MEETING

A meeting of general practitioners of West Ham was held at Forest Gate on November 19 to discuss "the necessity for united and sustained action in making operative the requirements of general practitioners as a body in view of possible alterations in medical practice due to rapidly changing economic conditions." There was a good attendance, eighty-three practitioners being present. In opening the meeting Dr. R. POORS, the chairman, discussed the raising of the income limit for N.H.I.; the urgent problem of the medical care of dependants of members of the Forces; the inadequacy of the recent addition to the N.H.I. capitation fee; the fact that less than 5% of the population earned more than £500 per annum; the effect of increasing income-tax burdens on the individual patient; and how these factors must influence the future of medical practice. Dr. P. INWALD of Islington described what had been done in his district and the City area in organizing the doctors. Dr. H. BOYD welcomed the meeting as it showed an awakening professional interest in the social and economic problems affecting medical practice. He also drew attention to a suggestion of the B.M.A. as to the desirability of forming discussion and study groups for planning future medical progress.

In the general discussion which followed a number of speakers stressed the need for organization among general practitioners in order to make the wishes of the largest body of medical opinion in the country operative through the leading medical organizations. The following resolution, proposed by Dr. H. HANSON, was carried unanimously:

"That a co-ordinating committee be elected by the general practitioners of West Ham, to link up with other practitioner co-ordinating committees throughout the country, to watch over the interests of general practitioners by every accepted means, and to formulate their requirements and forward them to the Medical Planning Commission."

Doctors from East Ham who were present stated that they wished to associate themselves with the resolution. A committee of twelve was elected, and was instructed to get to work as soon as possible and report progress at the next meeting, which will be held at an early date.

Correspondence

Certificates for Change of Work

SIR,—May I with respect ask practitioners to exercise very great caution in giving certificates in support of application for change of work. There is an immense amount of change from one factory to another or from one occupation to another, especially among younger people, which is entirely unnecessary and frivolous, and wasteful of both the young people's time and energy and of the nation's war effort. In factories producing small parts of hard steel for war purposes, for example, a thick oil, not an emulsified oil, must be used for lubrication. A small factory with a few hundred workers will use many thousands of gallons of such oil in a week. A residual amount of dermatitis is almost unavoidable in such factories, but with care on the part of the workman and the devoted attention of nurses attached to such firms it need not cause incapacity for continued work.

I suggest that practitioners should inquire of an applicant for a medical certificate in order to get out of such work whether he has had any treatment lately for the condition, of what nature, and whether it was shown to the nurse for her to exercise her best efforts upon it. One should beware of the patient who wants only a certificate, not any treatment, for the condition on account of which application for change of work is sought. Sometimes one meets a patient who says quite frankly, "I don't want this condition cured, for then I should have no ground for getting a change"; or "I don't want a job in which I have to be careful not to get dermatitis. I want a job in which I can be careless and not get dermatitis." Responsible practitioners should make the appropriate answer to such talk, and they will also not drag in vague general terms like "general debility" and "debilitating anaemia" (without having the blood examined), or irrelevant facts like defective vision, which can be corrected in the present job or, if not corrected, will be taken to the next one. (I am, of course, not speaking of fatigue, which is a very real and serious condition, but one better corrected, in my experience, by a rest from all work, not a change of job.) One might bear in mind that one settler removed from a factory may stop the work of five or six operatives making small parts.

May I suggest also that it is bad practice to issue a medical certificate in a case of possible industrial disease on the strength of a bare possibility for the sake of fighting for it? Wartime industry cannot stand fights for the sake of a fight. In this connexion, further, it is contrary to public policy to allow an applicant to say or think that after all the examining surgeon of factories, or the medical inspector of factories, is the employer's doctor, with opinions coloured accordingly. The applicant's doctor is his doctor in the sense that with a little trouble the applicant can go to another for his support. But the examining surgeon and the medical inspector of factories are not chosen by any employer, and cannot be got rid of by any employer in order to choose another.—I am, etc.,

London, N 15, Nov. 23.

E. H. STRANGE.

Remedying the "Worst Abuses"

SIR,—Dr. A. Piney (in a letter in the *Journal* of November 22) asks for the causes of the present ills of practice. It would appear that there are remote causes—the influence of politics exerted by the approved societies—and local causes—the administrative financial difficulties which impede the logical development of the N.H.I. system. Only after removal of the basic cause by replacing the approved societies by a State Department can a consideration of the local causes be undertaken impartially.

Whether or not a State service is the requisite remedy for the ills—and it is here submitted that its reception by the public would be hostile, as an interference in what is always a personal matter, compared with other State services, actual or potential, which are of an impersonal nature—all remedies will turn on the available finance and on how this is used to remove the practical basic difficulty of the present system, which is the lack of time at the practitioner's disposal for work and play. This is due to his having to take on more patients than he can cope

with efficiently owing to the small capitation fee, and can only be remedied by so increasing the fee that the restriction of his activities by curtailing his list would be justified.

To increase the money the contributions must be raised. This has been done several times, but the increase has always been for services other than medical. At the moment only 3d. out of the weekly 1s. 10d. is allocated to medical service and drugs, with their administration. An increase in the basic fee would entail no extra charges for administration or drugs, so that an increase of 2d. weekly to the present contribution would more than cover the rise in fee, which, it is suggested, should be to 17s. Surely no one could complain of paying 5d. weekly for medical service and drugs. Tackle the administrative difficulties of including all dependants in the scheme, with perhaps some relief for numbers in families, and the whole could surely be put upon a sound basis.

Once having obtained the necessary finance and cleared away the politician, many ways of reorganizing the present system exhibit themselves without going so far as a State service. As a broad outline it is submitted that there should be three types of practice: the solely private, the solely panel, and the third a mixture of the two. The first needs no discussion, as the practitioner would carry on as now. The second would be limited to 2,500 patients at the proposed fee of 17s., and the third to 1,500 at the same fee.

The above would seem to remove the worst abuses of the present system, which arise from lack of time at the practitioner's disposal, resulting in sweated labour for many doctors, hasty treatment for many patients, and little preventive treatment from the State's viewpoint.—I am, etc.,

Lincoln, Nov. 23.

S. WRAY.

"Present Discontents"

SIR,—A letter signed by Mr. M. Tree, F.R.C.S., of the Birmingham and Midland Eye Hospital was published in the *Supplement* of November 15. As it was addressed from this hospital the Medical Board wish it to be understood that the letter conveys the personal view of the writer, and is not to be regarded as representing the views of the Medical Board or of the honorary staff of the hospital.—I am, etc.,

E. B. ALABASTER.

Chairman of the Medical Board,
Birmingham and Midland Eye Hospital.

Nov. 28.

Medical Services of H.M. Forces Appointments

ROYAL NAVY

Surgeon Captain H. F. Briggs has been placed on the Retired List. Surgeon Lieut.-Commander W. J. M. Sadler to be Surgeon Commander.

Surgeon Lieut. A. P. C. Clark (Emergency) to be Surgeon Lieutenant-Commander (Emergency).

Surgeon Lieut. R. W. G. Lancashire, D.S.C., to be Surgeon Lieutenant-Commander.

Surgeon Lieut. B. W. Walford has been transferred to the Permanent List. (Substituted for the notification in the *London Gazette* dated October 17, 1941.)

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieut. W. I. D. Scott to be Surgeon Lieutenant-Commander.

Acting Surgeon Lieut.-Commander D. R. Maitland to be Surgeon

at J. Phillips to be Surgeon Lieutenant.

Lieutenants: I. Ashforth and D. Tolmie.

Surgeon Lieuts: J. Watt, M. N.

O'Riordan, F. L. Davies, J. R. A. Hall, R. L. Canney, A. R. H. Oakley, W. E. Gill, J. T. Aldren, D. Chisholm, W. Leckie, P. J. McEnroy, A. C. Clark, P. J. Curran, and L. B. Cohen to be Temporary Surgeon Lieutenants.

ARMY

Major-General W. B. Purdon, D.S.O., O.B.E., M.C., K.H.S., late R.A.M.C., having attained the age for retirement, has retired on retired pay.

Colonels (Temporary Brigadiers) D. T. Richardson, M.C., K.H.S., late R.A.M.C., and L. T. Poole, D.S.O., M.C., K.H.P., late R.A.M.C., to be Major-Generals (supernumerary).

Colonel D. C. Monro, K.H.S., late R.A.M.C., to be Major-General (supernumerary).

Colonel R. E. Barnsley, M.C., late R.A.M.C., to be Major-General.

Colonel G. A. Blake, late R.A.M.C., has been granted the acting rank of Major-General.

Lieut.-Colonel (Temporary Brigadier) J. Walker, M.C., from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel (Temporary Colonel) H. Walker, O.B.E., M.C., having attained the age for retirement, has retired on retired pay and remains employed.

Lieut.-Colonel D. C. G. Ballingall, M.C., has retired on retired pay on account of ill-health, and is granted the rank of Colonel. (Substituted for the notification in the *Supplement* to the *London Gazette* dated June 13, 1941.)

Majors (Temporary Lieut.-Colonels) D. H. Murray and E. Underhill to be Lieutenant-Colonels.

Major E. A. Stroud has relinquished his commission, retaining the rank of Major.

Captains (Temporary Majors) A. P. Trimble and A. D. Low to be Majors.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel E. L. Sandiland, T.D., has relinquished his commission on ceasing to be employed, and has been granted the rank of Lieutenant-Colonel (Brevet Colonel).

Captain G. Morgan has relinquished his commission on account of ill-health, and is granted the rank of Major.

Captain J. A. Blain has relinquished his commission on account of ill-health, and retains his rank.

Supernumerary for Service with Liverpool University Senior Training Corps (Medical Unit).—Lieut.-Colonel (Brevet Colonel) A. A. Gemmell, M.C., T.D., to be Lieutenant, and has relinquished the rank of Lieutenant-Colonel (Brevet Colonel).

Supernumerary for Service with Liverpool University Senior Training Corps (Medical Unit).—Captain W. J. Dilling, late R.A.M.C., to be Major, and to command the unit. (Substituted for the notification in the *Supplement* to the *London Gazette* dated October 31, 1941.)

Supernumerary for Service with Glasgow University Senior Training Corps (Medical Unit).—A. Slessor to be Lieutenant.

ROYAL AIR FORCE

Flying Officer R. Macpherson to be Flight Lieutenant (War Substantive).

Miss M. I. McNaughton-Jones, Mrs. A. L. J. Dovey, and Miss J. H. Morton have been promoted to the relative rank of Flight Lieutenant (War Substantive).

Brenda E. Linck to be Medical Officer (Emergency) for employment with the R.A.F. with the relative rank of Flying Officer.

DENTAL BRANCH

Flying Officer F. S. Krusin, M.R.C.S., L.R.C.P., to be Flight Lieutenant (War Substantive).

T. Dagger, M.R.C.S., L.R.C.P., to be Flying Officer (Emergency).

INDIAN MEDICAL SERVICE

Lieut.-Colonel J. Findlay has retired.

EMERGENCY COMMISSIONS

To be Lieutenants: G. V. Faulkner, T. H. S. Smith, A. D. Dyson, P. Jacobs, W. M. Jones, D. A. Maclean, and F. A. Whittock.

COLONIAL MEDICAL SERVICE

The following appointments are announced: J. H. Pierre, F.R.C.S., Medical Officer, Grade B, Trinidad; W. G. Wickremesinghe, M.R.C.S., L.R.C.P., Assistant Director of Sanitary Services, Ceylon.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following postgraduate courses: (1) Demonstration on the Fundus Oculi (specially suitable for M.R.C.P. candidates) on Tuesday, January 6, 1942, at 3 p.m., at the out-patient department of the West End Hospital for Nervous Diseases; (2) week-end course on "The Rheumatic Diseases" (suitable for general practitioners and members of H.M. Forces), on Saturday and Sunday, January 10 and 11, 1942, at the Rheumatic Unit, St. Stephen's Hospital (L.C.C.), Fulham Road, S.W.

APPOINTMENTS

EXAMINING FACTORY SURGEONS.—D. Cameron, M.B., Ch.B., for the Plymouth East District (Devonshire); Mrs. Alexandra W. Lloyd, M.B., Ch.B., for the Stewarton District (Ayrshire).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTHS

BOLAM.—On December 7, at 30, Osbaldeston Gardens, Gosforth, Newcastle-upon-Tyne, to Betty, wife of Mason Bolam, M.D., a daughter.

HOOD.—On November 8, 1941, at Colombo, Ceylon, to Barbara (née Boyle), wife of Surgeon Lieut. Martin C. Hood, R.N.V.R., a son.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 27 1941

WAR NOTICE

Payment for Sessional Attendance at First-aid Posts

As from January 1, 1942, the remuneration of doctors for sessional attendance at first-aid posts and mobile first-aid units will be according to the following scale, which has been agreed with the Central Medical War Committee:

(a) For an attendance for a period not exceeding half an hour: 10s. 6d.

(b) For an attendance for a period exceeding half an hour but not exceeding one hour: £1 1s.

(c) For an attendance for a period exceeding one hour: £1 1s., plus 10s. 6d. for each additional hour or part of an hour.

These payments are not subject to the maximum of £3 3s. per day operating under the existing arrangements.

Circular 2536 of the Ministry of Health states that the new scale should apply in all cases in which sessional fees are payable for the first-aid treatment of casualties, and that local authorities should give notice of the change as soon as possible to all doctors concerned. The new scale corresponds substantially to that adopted for the payment of practitioners called to attend cases of illness or accident in public air-raid shelters or rest centres.

The circular also states that doctors called to their first-aid posts to attend Civil Defence workers injured in the course of their duties will be paid on the same basis as for air-raid casualties, and the above scale will, therefore, apply.

CENTRAL MEDICAL WAR COMMITTEE,
B.M.A. House, Tavistock Square, W.C.1.

GENERAL PRACTICE COMMITTEE OF THE B.M.A.

A full meeting of the General Practice Committee of the British Medical Association was held on November 26. Dr. S. Wand of Birmingham was elected to the chair for the session, and the Committee placed on record its high appreciation of the exceptionally valuable services rendered by Dr. J. W. Bone as chairman of the Medico-Political and General Practice Committees over a period of fifteen years.

Recommended Increase in Professional Fees

The principal matter before the Committee was the various questions which have arisen from the Council's recommendation that fees in private practice should be increased by 20%. That recommendation has been widely adopted by local units of the Association, but it has led to inquiries as to whether it should apply to contract practice arrangements in general, including Public Medical Services. The view of the Committee, as embodied in a recommendation to Council, was that it should so apply, and much of the meeting was occupied by discussing the conditions of various services. On the subject of fees for life assurance examinations, information was received that certain insurance offices have increased the maximum fee for medical examination for life assurance to 25s., which is approximately a 20% increase on the previous fee of one guinea. It was decided to recommend that representations be made to the Life Offices Association that, save in the cases in which similar action had been taken by individual offices, the fees for medical examination should be increased by not less than 20%.

The question of the remuneration of district medical officers and public vaccinators also came up for discussion here. This is a matter in which the Public Health Committee is interested, and, subject to the concurrence of that committee, it was proposed to advise Branches and Divisions to endeavour to secure

readjustment in the salaries of district medical officers in view of the burden of additional work in many areas, increased practice expenses, and the introduction of a new group within the scope of the service—namely, supplementary old age pensioners. A wartime percentage increase in the fees of public vaccinators was also advised.

An application for a 20% increase in the fees of police surgeons was also recommended as a course of action for Branches and Divisions, subject, of course, to the approval of the police surgeons in the locality. A further recommendation was that application be made to the National Deposit Friendly Society for a similar increase in the fees paid for the medical treatment of its members. With regard to Public Medical Services it was reported that a Special Public Medical Services Conference was held on December 9 to consider specifically the question of admission to membership of dependants of the new entrants to National Health Insurance with incomes up to £420 per annum.

A new matter was raised in the remuneration of medical officers to fire brigades, and it was proposed that the matter be taken up centrally with the Ministry of Home Security. The uniform scale suggested was 10s. 6d. as a fee for medical examination of new entrants; 10s. 6d. for rendering first aid to persons injured at fires, if the period of attendance did not exceed half an hour, with suitable additions for longer periods; and a capitation fee of 10s. per annum (without drugs) for attendance on members of the service, and 5s. for each medical report required, or 15s. per annum to cover any necessary reports.

It was reported that a meeting with representatives of the Ministry of Pensions to consider the question of sessional fees for members of medical boards had been arranged for the following day, and that proposals submitted in advance by the Department appeared to offer a favourable scale if assurance was given that there would be regular work on an advance time-table.

Certification

The Secretary reported progress in his efforts to prevent or lessen the demands upon members of the profession for certificates. It had been necessary to approach a number of Government Departments—six or eight—and a little patience was still required before the whole question could be regularized. But he hoped to ensure that practitioners would not be troubled with requests for certificates at least in those cases in which the certificate of another person would serve the same purpose, and also to make it incumbent upon the Departments to consult the Association before any new form of certificate was issued to which the signature of a doctor might be required.

First Aid in Mines: Morphine Administration

A memorandum which had been submitted to the Secretary and was brought by him before the Committee concerned the proposed administration of morphine by first-aid men in mines. It was stated that in the case of severe injuries underground there might be, owing to the difficulty and distance of the working place, delay in obtaining the service of a doctor, and that in such circumstances specially instructed first-aid men should be allowed to administer 3/8 grain morphine in tablet form under the tongue. The Committee concurred in this suggestion.

War Damage Act, 1941.

A matter of considerable importance affecting those members of the profession who dispense medicines has arisen out of the provisions of the War Damage Act, 1941. The question was raised with the Board of Trade as to whether doctors' drugs and medicines are insurable under the Business Scheme created

by Part II of this Act, or under the Commodities Scheme of the War Risks Insurance Act, 1939. The Board has expressed the opinion that if a doctor runs his own dispensary, the drugs and medicines are insurable under the Commodities Scheme, otherwise they are insurable under the Business Scheme. The decision that doctors' drugs and medicines are insurable under the Commodities Scheme as goods supplied means that doctors will be required to stocktake monthly, and to work out and send in their premiums monthly. It is understood that dressings are treated differently and can be insured under the Business and Chattels Section. The importance of the opinion expressed by the Board of Trade lies in the fact that members of the profession who dispense their own medicines are held to be selling medicines and drugs as they are sold in a chemist's establishment. The Committee has obtained the opinion of Counsel, Mr. Gerald Gardiner, on the subject, but Counsel

Counsel's opinion has been forwarded to the Board of Trade. He is of opinion that practitioners who dispense their own medicines are not "carrying on business" for the purpose of the War Damage Act, 1941, and that a practitioner's medicines, drugs, etc., are insurable under the Business Scheme and not under the Commodities Scheme.

Counsel's opinion has been forwarded to the Board of Trade, and the Department has been asked to reconsider in the light of Counsel's opinion its earlier decision that drugs and medicines, where supplied by a doctor who conducted his own dispensary, were insurable under the Commodities Scheme and not the Business Scheme.

GENERAL MEDICAL COUNCIL DISCIPLINARY PROCEEDINGS

(Concluded from p. 107)

Misleading Certificates

The Council considered the case of Alexander Cannon, M.D., registered as of Harley Street, who was summoned on the charge that on July 15 last he signed and sent to Herbert Latreille, a district warden of Beckenham, a certificate or other document stating:

"Mr. Herbert Latreille is under my care and requires an immediate rest owing to the state of his nervous system, and I have ordered him away for a rest from the 19th instant for a period not less than three weeks. In my opinion it would be criminal to allow him to continue his work at present."

whereas he had neither seen nor examined this person at any time during 1941. He was also charged with having on October 22, 1940, sent to the same person a certificate stating that Latreille was

"suffering from nervous exhaustion and sympathetic atonia and urgently requires 14 days' rest from all duties and complete change of air away from England."

whereas he had neither seen nor examined this person since March, 1940.

Dr. Cannon conducted his own defence.

Mr. W. J. Sampson, Mayor of Beckenham and chief warden, gave evidence in support of the complaint. In reply to the Council's solicitor, he said that Latreille applied for sick leave in July, 1941, and produced a certificate from a doctor—not Dr. Cannon—but leave was not granted. He was, however, found to have due to him a certain amount of annual leave. On July 18 Latreille sent a certificate which he said that he had received by registered express mail from Dr. Cannon, who was in the Isle of Man. The certificate read as set out in the charge, and as a result the application for sick leave was granted. He understood the certificate to mean that Latreille was undergoing a course of treatment prescribed or supervised by Dr. Cannon. In reply to Dr. Cannon witness said that he had asked for information as to when the doctor had last seen Latreille. He was also asked why, not being satisfied with this information, as he had stated, he did not communicate with Dr. Cannon himself. The witness replied that he had a duty to perform and that, the certificate having been presented in circumstances which did not appear to be quite in order, he and his colleagues on the committee decided that the certificate should be forwarded to the appropriate authority. In reply to a member of the Council he said that when he saw that the certificate was issued in the Isle of Man he never supposed that the doctor had examined the man before giving the certificate,

though he had an idea that at some previous time Latreille had been Dr. Cannon's patient.

Dr. Cannon, in his defence, called Mr. Herbert Latreille, who said that he telephoned Dr. Cannon in October, 1940, and again in July, 1941, with regard to his condition, and when the Emergency Committee at Beckenham refused to accept the other doctor's certificate, he appealed to Dr. Cannon as his medical attendant for four and a half years to help him. He asked him to make his statement strong so that he could get the necessary leave. In due course he went to the Isle of Man and placed himself under the direct care of Dr. Cannon, from whom he received a proper certificate on August 8.

Dr. Cannon, in evidence on his own behalf, said that for fourteen years he had been practising his specialty, the treatment of mental and nervous diseases. He was going on to mention his method of hypnotic contact and diagnosis at a distance, when the President said that it was not relevant.

The President: Supposing on your certificate you had stated the facts as set out in your letter to the Council, that you had issued the certificate after a hypnotic diagnosis through a third party, from the Isle of Man to Beckenham, do you think that would have had the same weight with the person who read it?

Dr. Cannon: I put it in this way, Sir: If the person who read it had the least doubt, he was in a position to communicate with me; I am quite confident that I did issue that certificate knowing the facts.

The Legal Assessor: You think "supervision," which in your view is the implication of the words "under my care," includes hypnotic contact between the Isle of Man and Beckenham? If you had intended that anyone should understand that you should have put it in your certificate.

Dr. Cannon: I could have done so.

The Legal Assessor: But you did not do it and thus prevent misunderstanding?

Dr. Cannon: The man was coming to see me.

The respondent went on to point out that the certificate showed clearly that it had been issued in the Isle of Man, and he said there could have been no doubt in the minds of those for whom it was intended that it was issued by the doctor without seeing the patient.

After the Council had deliberated *in camera*, the President addressed Dr. Cannon as follows:

I have to announce that the facts alleged against you in the Notice of Inquiry have been proved to the satisfaction of the Council. The Council cannot avoid the conclusion that the certificates signed by you in your professional capacity which form the subject of the charge were certificates of the type stigmatized in paragraph (1) of the Warning Notice as "untrue, misleading, or improper."

This paragraph is presumably within your knowledge, and the attention of the profession was drawn to its special importance under war conditions by an announcement published on behalf of the Council in the professional journals in April, 1941.

The Council regard your action in giving the certificates as a serious breach of the trust which Parliament has confided to the members of the medical profession. They have listened to the description of the circumstances in which these misleading and improper certificates were given by you. They do not regard that as offering any excuse for your laxity in giving them. They take a grave view of carelessness in issuing certificates required by public authorities; but from your statements they are prepared to believe that you signed the certificates not from any perversity or desire to falsify but from a mistaken view of your duty and an error of judgment.

Taking that into account, and believing that the warning you have received will be sufficient, they have not directed the Registrar to erase your name from the *Medical Register*.

Professional Relationship and Adultery

The Council considered the case of Eric Dickens Spackman, registered as of Shirley Road, Worthing, who appeared on the charge of having committed adultery with Barbara Pepper, a married woman, of which adultery he was found guilty by decree of the Divorce Court dated February 3, 1941, and made absolute on August 26, 1941, in the case of *Pepper v. Pepper* (Spackman cited), in which he was in the respondent's answer to the petition cited as co-respondent; and that he stood in professional relationship with the said Barbara Pepper at all material times.

Mr. Oswald Hempson, who appeared for Mr. Spackman on behalf of the Medical Defence Union, admitted the professional relationship but disputed the adultery and asked leave to call additional evidence on this point. In answer to the Legal Assessor, he admitted that he was asking the Council to go behind the finding of the Divorce Court, and that the additional

evidence which he wished to call could, with reasonable diligence, have been called in the divorce action.

After a short session *in camera*, the President announced that the Council were not prepared to hear fresh evidence. Mr. Hempton therefore contented himself with commenting on certain passages in the shorthand note of the divorce proceedings, and read a number of testimonials, including one from Sir Walter Langdon-Brown, a former member of the Council, and a petition signed by 526 of Dr. Spackman's patients. He also called Dr. Mackintosh, Dr. Spackman's partner, who gave evidence on his behalf.

The Council found that Dr. Spackman had been guilty of infamous conduct in a professional respect, and directed the erasure of his name.

Alleged Fraud

The Council considered the case of William Allan, registered as of Park Road, Oldham, who was summoned on the charge that at the Sheriff Court, Edinburgh, on January 13 last he was convicted of two charges of fraud, obtaining board and lodging to the value of £14 4s. 4d., and sentenced to fourteen days' imprisonment, and at the same court on February 14 of fraud, obtaining £5 by means of a worthless cheque, and sentenced to sixty days' imprisonment.

The Council's solicitor said, in regard to the first conviction that Dr. Allan went into two different hotels in his uniform as captain in the R.A.M.C., said that he was passing through Edinburgh on leave and that he was short of cash, and tendered cheques which were returned marked "R.D." After serving the sentence on this conviction he called at the local bank, told the same story, and cashed a cheque for £5.

Dr. Allan, in reply to questions from the President and members of the Council, said that he did not wittingly cash cheques which he knew were worthless. He had no reason to suppose they would not be cashed, and in fact money had since been paid into his bank exceeding the value of the cheques. His Army pay at the time was still going on, and he had money coming in from his practice under the B.M.A. Protection of Practices Scheme. The money, however, came in irregularly; sometimes he was notified and sometimes not. Although his commission in the Army terminated at the beginning of 1941 he was still receiving dribbles of pay and allowances down to the present November. He never received any passbook or pass-sheets from the bank. He was in a very low and dispirited state at the time of these happenings, and had since spent six months in hospital, from which he was discharged four weeks previously completely cured.

The President announced that the Council did not see fit to direct the Registrar to erase the name.

Drunkenness and Cognate Offences

Several practitioners were summoned before the Council on convictions for drunkenness and cognate offences, but only two names were erased. The first was John Black, registered as of Stanley Road, Bootle, who was summoned on two convictions of having been drunk and disorderly, and also one conviction of obtaining credit by means of fraud. His case had been previously twice adjourned owing to his non-appearance. He did not attend on this occasion, and after proof of service of the notice and of the convictions the Council directed the erasure of his name.

The other erasure was that of John Mackay Young, registered as of Albany Street, Regent's Park, who had been convicted of driving a motor car while under the influence of drink to such an extent as to be incapable of having proper control, and had been sentenced to three months' imprisonment with hard labour. Dr. Young had been before the Council on a previous occasion. Mr. Oswald Hempton mentioned certain extenuating circumstances, and expressed his client's sincere regret, but the Council came to the decision stated.

In two other cases the Council found the facts proved, but postponed judgment for twelve months on the usual conditions. The first was that of Jerome Thaddeus O'Leary, registered as of St. Ann's Road, Tottenham, who had been twice convicted of being in charge of a motor car while under the influence of drink. Mr. Oswald Hempton, for the respondent, pointed out that the convictions were in 1938 and 1939. Immediately on outbreak of war he had offered his services and served for a time, but broke down in health and was in hospital from April to November, 1940. Several testimonials were put in as to the entire propriety of his behaviour since the date of these convictions.

The other case in which the Council placed the practitioner on probation for one year was that of Daniel Joseph Purcell, registered as of Nass, Co. Kildare, who appeared on two convictions, one in 1936 and the other in 1941, of being in

charge of a motor-car while under the influence of drink. He was defended by Mr. Alban Gordon, counsel, who mentioned extenuating circumstances.

In three further cases, on similar convictions, the Council did not see fit to direct erasure of the name. Florence Joseph O'Driscoll was summoned on having been convicted, in 1939, of being drunk and disorderly and of wilful damage. Dr. O'Driscoll was at sea, and it was decided to go into his case in his absence as he had submitted testimonials, which were regarded as satisfactory. He had previously been before the Council, which then decided not to erase his name. The second case was that of Frank Fawcner Langridge, registered as of Kenton Road, Kenton, who had been found guilty by a general court-martial of being drunk when on active service and sentenced to be dismissed from His Majesty's Service. In evidence before the Council Dr. Langridge said that from 1928 to 1936 he was practising in India, where he contracted malaria, a condition from which he was suffering at the time of these offences, but which was not taken into account by the court-martial. He admitted that he was drunk on this occasion, having taken alcohol as well as quinine. Testimonials were put in, and the case was dismissed.

The third case in which the Council took this course was that of Eric Llewellyn Williams, registered as of Roath Park, Cardiff, who had been found guilty by a general court-martial of having been unfit for duty by reason of previous indulgence in alcoholic stimulants. The respondent said that on the occasion of the alleged offence he was a sick man, and shortly after the court-martial a medical board recommended his discharge from the Army as medically unfit. He had high blood pressure and symptoms of kidney trouble. Medical evidence to that effect was given to the court-martial, but he did not think sufficient weight was attached to it. Within the last eighteen months alcohol had had an extraordinarily allergic effect upon him, although previously he was able to take normal quantities without ill effects. After the medical board he entered a nursing home for three months' treatment, from which he had derived great benefit, and since that time he had been a teetotaler. In this case also the Council did not see fit to direct erasure.

In three other similar cases the Council postponed the hearing, in two because the practitioners had not been traced, and in the third because the conviction was the subject of a pending appeal.

Correspondence

Democratic Machinery

SIR,—I have read with interest the pamphlet, D.4, issued by the Secretary of the British Medical Association. Its contents have gone some way to reassure me that the opinions of B.M.A. members, expressed either through your columns or at various meetings inside and outside the Divisions, are being considered by the Representative Body and Executive. I have always maintained that the Association is a reasonably democratic body, which desires to serve the interests of its members, and indeed of all the profession, to the utmost of its ability. Nevertheless, from reports and letters published in the *Journal*, it has been obvious that there has been a certain amount of dissatisfaction expressed by its members, many of whom are general practitioners.

I believe that this dissatisfaction can be ascribed to three main reasons:

1. The present system under which a general practitioner has to gain his livelihood, often a precarious one, is so irksome and gives him so little time for relaxation that he is unable to devote his leisure to a consideration of the difficulties and injustices, and to meet his colleagues in order that they may jointly draw up a reasoned statement of their conditions for consideration by the Executive. This is confirmed by the very poor attendances manifest at Branch and Division meetings. There is, I believe, no hope for any improvement in this state of affairs unless members can be made to realize that it is time for them to make a serious and concerted effort to meet and discuss their points of view.

2. Because of the first premise, it follows that the representatives cannot have a comprehensive knowledge of the general practitioner's difficulties. I note that this pamphlet points the way to these discussions, but I believe that they will result in the same lack of interest and enthusiasm until the profession is

confronted with an accomplished fact, such as recently occurred with the capitation fee. Only then will they cry out that their interests have not been adequately considered and safeguarded by the Association.

3. After reading the B.M.A. Year Book, it would be safe to assume that the vast majority of members have not the least idea of the workings of the British Medical Association, such as the election of members to the Representative Body and the various committees, and of their rights for the summoning of meetings, in order that matters of interest can be discussed before they die of inanition and thus give rise to erroneous assumptions by the Executive. With all due deference to our esteemed secretary, I would venture to suggest that this ignorance of the by-laws is the more likely reason why twenty out of twenty-three I.A.C. members were re-elected, rather than that the members were satisfied with its achievements.

All this preamble is set out in the hope that it will throw some light on the causes of the apparent failure of the Executive to represent the wishes of the body, and that some attempt will now be made to make every doctor, both member and non-member, conscious of the fact that if he does not take an active part in the forthcoming discussions he must accept the responsibility for any failure to reach a satisfactory solution. To this end, I believe, the Association should undertake a strong publicity campaign, directed by an experienced publicist, and that one or two pages of the *Journal* each week should have an arresting "set-up" which will bring home to its readers in an unmistakable manner the importance of the campaign.

As a further contribution to the stimulation of interest, it might be considered a good plan to have a weekly article in the *Journal* describing the conditions of medical practice in other countries, together with a statement of their achievements in the reduction of sickness and mortality rates. So many of the Allies have medical and governmental representatives that there should be little difficulty in obtaining suitable contributors. We should then be able to compare those other systems with our own, and extract from them the points which could be usefully applied to improve ours and, what is perhaps more important, to appraise their faults, and be sure that they are not introduced here.

I appreciate that this letter is very superficial in its contents, but if it does no more than indicate lines of thought which have not as yet appeared in the *Journal* it will have achieved its object.—I am, etc.,

WILLIAM W. FOX.

London, N.6, Nov. 30.

The Panel Doctor's Advocates

SIR.—The letter from the Secretary of the B.M.A. is a welcome innovation. It is appreciated evidently that there is a strong undercurrent of criticism among members concerning the scant consideration given to our Association by the Minister of Health in the matter of the new panel patients and milk certification. The Association did not consider it would be in good taste to press for better remuneration in wartime, but the Minister did not consider our feelings in his encroachment on private practice. His promises about full investigation "from the ground" will be repudiated by his successor unless history fails to repeat itself.

It is clear that the Minister regards the Insurance Acts Committee as well-nigh impotent. He should be made to realize that present panel remuneration is being heavily subsidized by private practice. Surely after such setbacks the I.A.C. requires reorganization to give it power and make its influence felt. All praise to the twenty members of the committee who have been re-elected, but when shall we learn that we cannot get efficient representation from hard-working insurance practitioners doing I.A.C. work in their spare time and dashing up to London for brief periods? Release men from the responsibilities of practice, pay them a salary, and then we may get results. We lost our case in 1937 because we had working doctors pleading for us instead of the best advocates that money could obtain.

It has been stated that in order to coerce the Minister we should have had to refuse service, which would be unthinkable in wartime. I do not agree; other methods were available. We could have told the Minister that if he pressed his new panel patients upon us we should demand a surcharge of £1.00 per

from each such patient when he presented his card, and repeat the demand each year at his first attendance.

If the Association does not think insurance practitioners are sufficiently solid to enforce such a regulation the sooner a virile campaign is launched the better.—I am, etc.,

Preston, Dec. 1.

ROBERT SLATER, M.B., Ch.B.

Priority Egg Supplies

SIR,—I wish to protest against the extremely unfair discrimination in the matter of egg supplies to the patients of general practitioners. Certificates for extra eggs may only be issued in the case of patients suffering from typhoid (and paratyphoid) and dysentery (amoebic or bacillary) whilst under treatment in a hospital or similar institution. There is no law compelling patients with either typhoid or dysentery to enter a hospital for treatment if they wish to remain at home so long as there are adequate facilities for isolation and nursing at home, although it is a fact that all sanitary inspectors seem to do their best to persuade one's patients that they can be properly treated only in a hospital. I have often treated patients with dysentery at home. On one occasion I had eighteen cases at home at one time as the local isolation hospital was full. (This was in the country.) This refusal to allow extra eggs to such patients unless they are in hospital is another instance of the subtle underhand attempt on the part of "officialdom" to deplete the general practitioner's rightful income and prestige.

In the case of typhoid and dysentery both diseases are notifiable, so that all cases are automatically placed under the supervision of the local health authorities as well as the practitioner attending the case. This fact should be ample and sufficient safeguard for the Ministry of Food and Lord Woolton.—I am, etc.,

London, S.W.1, Dec. 4.

A. GILBY, M.B., B.S., D.P.H.

. The Secretary of the B.M.A. writes: At the request of the Ministry of Food the draft schedule of conditions for priority supplies of eggs was considered by a committee of the Association, and the opinion was submitted to the Ministry of Food that the words "whilst under treatment in a hospital or similar institution" should be deleted. The Ministry, however, has apparently not seen fit to accept our suggestion.

Dr. S. TERRY PYBUS writes: In my letter in the *Supplement* of November 29 (p. 98) I referred to a certificate for clothing for a baby. My attention has been drawn to the fact that I omitted to give the patient's National Registration number on my first certificate, and that it is required on the official form. As this number could have been supplied by the patient herself another certificate seems to be somewhat unnecessary, as the essential part of the certificate is that the woman is expecting to have a baby, and not her National Registration number! However, I shall be glad if the Editor will give space for this correction.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following postgraduate courses: (1) demonstration on the fundus oculi (especially suitable for M.R.C.P. candidates) on Tuesday, January 6, 1942, at 3 p.m., at the out-patient department, West End Hospital for Nervous Diseases; (2) week-end course on the rheumatic diseases (suitable for general practitioners and members of H.M. Forces) on Saturday and Sunday, January 10 and 11, 1942, at the Rheumatic Unit, St. Stephen's Hospital (L.C.C.), Fulham Road, S.W.

A military hospital medical society has arranged a week-end course in war medicine, to be held on Saturday and Sunday, January 3 and 4, 1942. On January 3 at 1.45 p.m., following an introductory address by the officer commanding, Colonel A. McKie Reid, there will be clinical demonstrations and a discussion on psychological problems. On January 4 at 9.30 a.m. there will be skin demonstrations, and nutrition in war and injuries of the chest will be discussed. The visiting lecturer will be Mr. H. Morrison-Davies.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Chippenham (Wiltshire) is vacant. Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by December 30.
